LECTURES

Allbutt, Prof T Clifford —
An Address (Abstract of) on the Historical Relations between Surgery and Medicine, delivered at the Medical Congress St Louis, on Sept 27th 1904 935

Balfour, Rt Hon A J —
A Presidential Address on Reflections Suggested by the New Theory of Matter, delivered before the British Association for the Advancement of Science at Cambridge on August 17th, 1904, 509

Ballance, Mr C A —
An Address entitled Some Remarks on the Application of the Principles of Surgery to the Treatment of Injury and Acute Infection when occurring within the Abdomen, delivered at the annual meeting of the Clinical Society of Manchester on Oct 4th 1904 1195

Barker Mr Arthur E —
An Address upon the Surgical Treatment of Acute Intestinal Obstruction, 809

Battle, Mr W H —
Clinical Lecture (Abstract of a) on the *Diagnosis of Osteo-Sarcoma of the Long Bones* delivered at St Thomas's Hospital on June 16th, 1904, 550

Beard Dr J —
A Lecture (Abstract of) on the Problems of Cancer, delivered to the class of Embryology in the University of Edinburgh on Oct 18th, 1904 1200

Bland Sutton Mr J —
The Purvis Oration on Abdominal Pregnancy in Women, Cats Dogs and Rabbits, delivered before the West Kent Medico-Chirurgical Society on Dec 2nd, 1904, 1625

Bowlby, Mr Anthony A —
A Clinical Lecture on Cases of Appendicitis delivered at St Bartholomew's Hospital on Feb 17th, 1904, 61

Bradford Dr J R —
The Croonian Lectures on Bright's Disease and its Varieties delivered before the Royal College of Physicians of London on June 7th 9th 14th and 16th, 1904
Lecture I 125
Lecture II 191
Lecture III, 283
Lecture IV, 354

Bradshaw, Dr T R :—
A Clinical Lecture on Two Cases of Hemiplegia, delivered at the Liverpool Royal Infirmary on May 31st 1904 134

Buzzard Dr Thomas :—
A Clinical Lecture on Remissions and Relapses [illegible]

An Address on the Future Relation of King's College to its Medical School and Hospital delivered at King's College at the Opening of the Medical Session on Oct 4th, 1904, 1000

Caiger Dr F Foord —
The Bradshaw Lecture on the Treatment of Enteric Fever, delivered at the Royal College of Physicians of London on Nov 15th 1904 1467

Church, Sir William Selby :—
Address in Medicine on Our Sanitary Needs, with Special Reference to the National Health delivered at the Annual Meeting of the British Medical Association at Oxford on July 27th, 1904 272

Collier Dr William —
Presidential Address on the Growth and Development [illegible]

Corner, Mr Edred M :—
P[illegible]

Dunn Mr H Percy :—
A Lecture on Infective Cyclitis (so-called Sympathetic Ophthalmia) delivered at the West London Post-Graduate College 436

Gowers Sir W R —
An Address on Insanity and Epilepsy in Relation to Life Assurance delivered before the Association of Life Assurance Medical Officers on Oct 5th, 1904, 1061

Heath, Mr Charles J —
An Address on the Restoration of Hearing after Removal of the Drum and Ossicles by a Modification of the Radical Mastoid Operation for Suppurative Ear Disease founded on the Experience of 400 Operations delivered before the Otological Society of the United Kingdom on Dec 5th 1904 1767

Klein, Dr E —
The Horace Dobell Lecture on the Life history of Saprophytic and Parasitic Bacteria and their Mutual Relation delivered before the Royal College of Physicians of London on Nov 22nd 1904 1477

Lane, Mr W Arbuthnot :—
An Address on the Operative Treatment of the Conditions of the Gastro-intestinal Tract which result from Chronic Constipation, 1635

Liebreich Prof Oscar —
An Address on the Relation of Therapeutics to Other Sciences in the Nineteenth Century, delivered at the International Congress of Arts and Sciences at St Louis U S A on Sept 24th, 1904, 1066

Lucas Mr R Clement —

LIST OF ILLUSTRATIONS.

Coloured.

Full-page plate in colours showing the Piroplasm of Donovan, Laveran, and Mesnil accompanying paper on Human Piroplasmosis by Major C. Donovan, I.M.S., 744

Seven figures illustrating the Downes Electro thermic Angiotribe, described by Dr. H. Macnaughton-Jones, 16, 17

An Aseptic Operating Cap designed by Mr. A. H. Burgess, 28

Four figures accompanying paper on an Examination of Apparatus Proposed for the Quantitative Administration of Chloroform by Dr. A. D. Waller and Mr. J. H. Wells, 77, 78, 79

Microphotographs of sections accompanying paper on Adenomyoma of the Uterus by Dr. S. J. Murdoch Cameron and Dr. A. Leitch, 85, 85, 87

Two portraits of a Patient with Ocular Defects Associated with Oxycephaly, under the care of Captain E. F. Gordon Tucker, I.M.S., 88, 89

Illustration of an Inhaler for the Administration of Ether and Chloroform or Ether Alone, described by Dr. W. J. McCardie, 154

Illustrations (1) of a Steel Meatometer, (2) of a Bi-bulbous Sound of Aluminium, described by Mr. James MacMunn, 154

View of Fruit Pickers' Shanties in Kent, 167; and of a Group of Pickers, 168

Five Illustrations of Prostates Removed from Patients accompanying paper on Total Enucleation of the Prostate by Mr. P. J. Freyer, 193, 202

Four figures illustrating the Radical Cure of Umbilical Hernia by Mr. B. G. Moynihan, 207

Diagram illustrating Operation for Regurgitant Bilious Vomiting after Gastro-enterostomy by Mr. W. H. Brown, 216

Illustration of Automatic Spring Retractor for Mastoid Operations, described by Mr. A. Roberts, 228

Two Illustrations of a new form of Apparatus for administering Ethyl Chloride alone or in combination with Ether, described by Dr. T. Lister Llewellyn, 228

Illustrations of a Set of Portable Retractors described by Mr. Brennan Dyball, 228

Temperature-chart accompanying paper on the Symptoms and Treatment of the Intracranial Complications of Otitis Media, by Mr. G. Heaton, 293

Photoprint of Patient illustrating a case of Multiple Sarcoma, described by Dr. Seymour Taylor, 298

Three Skiagrams illustrating a case of Traumatic Pneumothorax by Mr. R. Stanley Taylor, 300

Illustration of a combined Steriliser and Irrigator (a handy aid to cleanly midwifery), described by Dr. W. Salisbury-Sharpe, 306

Portrait of the late Sir John Simon, K.C.B., F.R.S., 321

Nine Illustrations accompanying paper on Diaphragmatic Hernia of the Stomach and on Torsion of the Small Omentum and Volvulus of the Stomach in association with it, by Mr. R. Lawford Knaggs, 358-363

Illustration of a Standard Dynamometer, described by Sir W. R. Gowers, 381

Illustration of a Head rest for Post-nasal Operations, described by Mr. Frank A. Nyulasy, 381

Diagrams showing the Methods of Division of Somatic and of Reproductive Tissue Cells, 467, 463

Illustration of a New Regulating Inhaler devised by Dr. Anton Dulling, 471

Four di[illegible] Lecture on the Pathology [illegible] ildren and their Relation [illegible] by Mr. Edred M. Corner, [illegible]

Two photoprints of Burnt Foot accompanying paper on Electrocution on the Railway and the Dangers of the Live Rail by Dr. Thomas Oliver, 516, 517

One photoprint and a skiagram illustrating a Case of Congenital Absence of One Tibia by Mr. H. Lennox Munro, 526

Illustration of Three Sizes of Dr. Landman's Silver Wire Artificial Vitreous, described by Mr. John R. Rolston, 527

Illustration of an Improved Apparatus for Auto-lavage of the Stomach, described by Dr. George Herschell, 532

Two illustrations of a New Inhaler for Administering any of the Usual Anæsthetics, described by Dr. T. Wilson Smith, 533

Chart showing the Incidence of Visible Lymph Follicles in the Conjunctivæ of Healthy School Children (Mr. Bishop Harman), 545

Portrait of the late Sir William Mitchell Banks, 567

Portrait of the late Dr. T. Gilbart-Smith, 567

Portrait of the late Sir Frederic Bateman, 567

[illegible] Skiagram [illegible] emur, 582; [illegible] by Osteo- [illegible] Femur, 583 [illegible] sarcoma of [illegible]

[illegible] Urachus after [illegible] n the Radical [illegible] ula) by Mr. B. [illegible]

Illustration of an All metal Cover-glass Holder, described by Mr. Edward Horder, 602

Three Temperature Charts of cases of Human Piroplasmosis, related by Major C. Donovan, I.M.S., 749

Two Microphotographs illustrating paper on Epibulbar Melanotic Sarcoma by Mr. J. Gray Clegg and Dr. I. Walker Hall, 750

Illustration showing Soft Rubber Catheter secured to Skin of Penis by Gauze and Collodion, accompanying paper on Ruptured Urethra by Dr. Henry Rutherfurd, 752

Illustration of an Improved Hagedorn's Needle Holder, described by Mr. Cecil H. Leaf, 769

Two illustrations of Combined Peritoneum Forceps and Wound Retractor, described by Dr. W. Blair Bell, 769

Illustration of an Audiometer for Noting the Auditory Appreciation in cases of Deafness and other Diseases of the Ear, described by Mr. St. Geo. Caulfeild Reid, 769

[illegible] paper on the Evolution of Man's Diet by Dr. [illegible] Ladder showing [illegible] sed Relation of [illegible] his evolution to [illegible] three great Advances in Man, 800; (5) the Hunt[illegible]

13 Temperature Charts of 13 Small pox cases treated by Red Light, 817; Four Portraits of Patients suffering from Small-pox, 818 (accompanying paper by Dr. T. F. Ricketts and Dr. J. B. Byles)

Four Figures showing (1) Sharp Trocar, (2) Blunt pointed Trocar, (3) Ear Speculum, and (4) Extra Long Speculum, accompanying paper on Inspection of the Antrum of Highmore by Dr. A. Brown Kelly, 819

Perimeter Chart of Left Visual Field of a Male, aged 50, illustrating paper on the Visual Fields in Tobacco Amblyopia by Mr. N. Bishop Harman, 821

Two Photoprints, (1) Anterior View showing the Loop of the Cæcum with Constriction formed by a Knot composed of Small Intestine and (2) Posterior View of the same, illustrating Clinical Note on a Rare Form of Intestinal Strangulation by Dr R. H Steen, 830, 831

Six Photomicrographs showing Radial, Brachial, and Middle Cerebral Arteries illustrating an Address on Arterial Sclerosis by Dr. Thomas D. Savill, 876-830

Four Temperature Charts of Cases of Fever in Children caused by the Indigestion of Certain Kinds of Carbohydrate Foods, described by Dr. Henry Davy, 882-884

Portrait of the late Surgeon-General James Jameson, M.D., C.B., K.H.S., LL.D., 927

Front V[illegible] Drawing of the Dissected Specimen.

[illegible] Longest Diameter, and (2) the [illegible] rease of Fibrous Tissue, illus- [illegible], described by Dr. J. F. Strick- [illegible] W. B. Anderton, 941, 942

[*List of Illustrations continued on next page.*

List of Illustrations—(*Continued*).

Drawing of an Apparatus devised to enable the Patient to Carry Out the Treatment of Constipation by the Injection of Olive Oil, described by *Dr. George Herschell*, 943

Drawing of Section of a New Steriliser for Surgical Dressings, described by Mr. Edward C. Stack, 958

Drawing of an Improved X-ray Tube for use with Static Machines, described by Dr. W. Salisbury Sharpe, 958

Illustrations (1) Glands of Lieberkuhn and Lymphatic Follicles taken from the Appendix (Longitudinal Section); and (2) Scheme of Cæcum, Ileo-cæcal Valve, and Appendix in Section, accompanying the Huxley Address on the Function of the Cæcum and Appendix, delivered by Sir William Macewen, M.D., F.R.S., 999

Five Drawings illustrating paper on Exclusion of the Intestine, by Mr. B. G. A. Moynihan, M S. Lond., F.R.C.S. Eng., 1011

Portrait of the late Professor Niels Ryberg Finsen, 1037

Photoprint of a Gigantic Renal Calculus occurring in a case related by Mr. A. Marmaduke Sheild, 1075

Skiagram showing Fracture-dislocation of Cervical Vertebræ in a case described by Mr. Ernest Ringrose, 1077

Portrait of a Native Boy of Southern Rhodesia with Gunshot Wound of the Right Side of the Face, described by Mr. P. H. Ward, 1081

Photoprint of Steerage Passengers on Board the s.s. *Ivernia* Shaving One Another, 1102

Chart of the Entrance to Port Phillip, Victoria, Australia, to illustrate the wreck of the *Australia*, described by Dr. J. W. Barrett and Dr. W. F. Orr, 1203

Three Microphotographs of Actinomycosis illustrating three cases of the Disease, described by Dr. Robert Knox, 1204

Portrait of a Little Girl with Actinomycosis of the Skin, admitted to the Victoria Hospital for Children, Chelsea, under the care of Dr. Walter Carr, 1216

Illustration of an Improved Mackintosh Sheet, described by Miss Margaret T. Stewart, 1223

Portrait of a Male Chinese with Congenital Absence of the Breast, described by Dr. G. Duncan Whyte, 1249

Illustration from Drawing of Condition discovered at an Operation Two Years Subsequent to Gastro-enterostomy, performed by Mr. Arthur E. Barker, 1278

Diagram illustrating a case of a Rare Variety of Malformation of the Anus, under the care of Mr. Stansfield Collier, 1283

Illustration of a New Transfusion Apparatus, designed by Dr. George H. Burford, for the *Performance of either Subcutaneous or* Intravenous Transfusion, 1292

Temperature Chart of a Patient suffering from Infective Myositis (Dr. J. Hill Abram), 1342

Diagrammatic Sketch of a Lint Model illustrating Double Intussusception of the Ileum into a Meckel's Diverticulum, 1347

Twelve Figures illustrating Appendicectomy and Intestinal Anastomosis accompanying a Lecture on *Some Practical Points in* Abdominal Surgery by Frederick Holme Wiggin, M.D., 1397–1400

Illustration of Apparatus for Administering Ethyl Chloride according to a Plan devised by Dr. Frederic W. Hewitt, 1413

Three Figures of Sphygmograms taken in a Case of Non-fatal Rupture of Aortic Aneurysm, described by Dr. C. H. Melland, 1414

View of Aortic Orifice showing Posterior Aortic Cusp and Thickened Calcareous Ring in a Case of Double Stenosis of the Aortic Orifice, under the care of Dr. Andrew Smart, 1418

Illustration of a Self-Retaining Tracheal Dilator, described by Mr. Douglas Drew, 1430

Illustration of Apparatus used by Dr. Frederic W. Hewitt for Nitrous Oxide and Ethyl Chloride Anæsthesia, 1486

Temperature Chart (Pyrexial Portion) of a Patient, aged three years, suffering from Small-pox and treated by Red Light by Dr. J. T. C. Nash, 1490

Two Figures showing [illegible] Mechanism of the Aortic Valves i[illegible] ,ram of Aorta of an Ox Open[illegible] 1492; Photographs showing [illegible] ere the Valves with all the Cusps are involved (Dr. R. J. Ewart), 1493

Portrait of a Patient with Accidental Vaccination Pustule on the Left Cheek simulating Anthrax (Dr. W. Sheen), 1495

Reproduction of Drawings after Photomicrographs of Sections of the Visual Cortex in the Mule-Deer and of the Visuo-sensory and Visuo-psychic Cortex in the Monkey (Macacus), 1557; Diagrams of Occipital Lobes of Macacus, Anthropoid Ape, and Human Subject, 1558; Brain of Macacus and Brain of Chimpanzee, 1559; illustrating paper by Dr. F. W. Mott on the Progressive Evolution of the Visual Cortex in Mammalia.

Reproductions of Drawings of Right Arm of Man, aged 50 years, showing Pendulous Growth of the size of a Child's Head at the Outer Side of the Right Elbow, 1563; illustrating a case of Neuro-fibromatosis, Sarcoma, and Death, described by Dr W. G. Richardson.

Microphotograph of a Section of Bone Marrow of a Hindoo Male showing Leishman-Donovan Bodies, 1564; accompanying notes on a few cases of Trypanosomiasis in Man by Mr. G. C. Chatterjee, 1564

Illustration of Apparatus for the Home Preparation of Aerated Waters by the "Soda Stream" System, 1577

Reproduction of a Humorous Illustration upon the Card Programme of a Smoking Concert held in Leeds, a Figurative Representation of the Load of Medical Education and the Fifth Year of Medical Study, 1583

Illustrat[illegible] Purvis Oration on Abdominal [illegible] Dogs, and Rabbits, by Mr. J. [illegible]ppy in its Amnion which had [illegible] of a Retriever Bitch; (2) A Fœtal [illegible]losed in its Amion, 1626; (3) A Gravid Fallopian Tube in which the Fœtus had been slowly extruded from the Tube, 1626

Photoprint of complete Cast of Stomach and Temperature Chart in a case of General Tuberculosis in which a complete Cast of the Stomach was vomited; case under the care of Mr. Edward Swales, 1639

Illustration of Forceps (originally devised for the extraction of gall-stones) used to remove a fruit stone which had been lodged in the right bronchus for five days; case under the care of Mr. W. Morley Willis, 1641

Photoprint of Midwives' Bag and Contents made at the suggestion of Mr. Alfred W. Hayles, 1647

Illustration of a new Uterine Mop, made at the suggestion of Dr. S Jervois Aarons, 1647

Portrait of the late Dr. George Vivian Poore, 1673

Two diagrams representing Process of Progressive Fixation of the Large Bowel, 1695; diagram representing Changes which the Large Bowel undergoes in consequence of Constipation, 1696 accompanying an Address on Chronic Constipation, by Mr. W. Arbuthnot Lane.

Illustration of Kidney [illegible]d Microscopical Section of Same showing Simple Villous [illegible]apilloma accompanying paper on Benign Villous Tum[illegible] the Renal Pelvis, by Dr. H. Savory and Mr. W. Giffo[illegible]sh, 1702

Diagram showing [illegible]ndition of the Stomach at the Time of Operation for Co[illegible]genital Hypertrophic Stenosis of the Pylorus, described by Mr. A. E. Maylard and Dr. John Anderson, 1710

Portrait of Anencephalous Monster described by Mr. H. Beattie, 1713

Illustration of *Hand power* Oto-Masseur *made* at the suggestion of Mr. Richard Lake, 1727

Illustrations of a Complete Apparatus for Venous and Subcutaneous Infusion in Steriliser, with Improved Venous Infusion Cannula, made according to the directions of Dr W. Blair Bell, 1728

Illustration of a new Thermo Cautery invented and made by Mr. W. H. Beach, 1728

Photoprints (1) of Patient's Head enveloped with Rubber Sheet Cap with the exception of Affected Ear and adjoining Skin showing through an Aperture; (2) Burrs, Gouges, Mallet, Meatus Separator, Periosteum Raiser, Probe-pointed Scissors, and a Comb, 1767; (3) Antrum Probes, Operating Probes, Sponging Forceps, and Suture Scissors, 1768; (4) Curettes, Specula, Spoon Forceps, Stapes Nipper, and Retractors, 1768; accompanying an Address on the Restoration of Hearing after Removal of the Drum and Ossicles by a Modification of the Radical Mastoid Operation for Suppurative Ear Disease, delivered by Mr. Charles J. Heath

Photoprint of a Full-length Figure of a Lady exhibiting an Invalid's Nightdress made according to a pattern designed by Mrs. E. *Francis*, 1793

Illustration of a Lumbar-puncture Syringe Case described by Dr. C. Christy, 1837

END OF THE SECOND VOLUME FOR 1904.

Printed and Published by the Registered Proprietors at No. 423, Strand, and Nos. 1 and 2, Bedford-street, Strand, in the Parish of St. Martin-in-the-Fields, Westminster, in the County of London.—Saturday, Jan. 7th, 1905.

A Clinical Lecture

ON

DECEPTIVE SIGNS OF IMPROVEMENT FOLLOWING UPON SEPTIC INTOXICATION IN ACUTE APPENDICITIS, ESPECIALLY IN YOUNG PEOPLE.

Delivered at St. George's Hospital Medical School on Nov. 3rd, 1903,

By Sir WILLIAM H. BENNETT, K.C.V.O., F.R.C.S. Eng,

SENIOR SURGEON TO THE HOSPITAL

Gentlemen,—It will be found that the clinical aspect of many of the surgical diseases with which we have to deal is often very different in young and growing subjects from that which is seen in those whose development has been completed. In appendicitis this is especially the case and it so happens that lately we have had several instances which illustrate a certain type of the disease in *young subjects which is a very dangerous* one and therefore well worthy of a little consideration I have already spoken recently about the matter in the wards in the course of the ordinary clinical classes, but there are two or three special points which I am anxious to discuss more fully and the present lecture gives me an opportunity for doing this.

The first case to which I must call your attention is that of a boy, aged 15 years, who is in the FitzWilliam Ward, having been admitted on Oct. 19th. Four days previously he had been seized with the ordinary signs of appendicitis, that is to say, acute pain in the abdomen, vomiting, some tenderness, especially over the right iliac region, some distension, together with constipation which after a dose of castor oil was followed by some diarrhœa. I saw him in the ward directly after he was brought to the hospital and he was obviously suffering from appendicitis. He had a flushed face with dark lines underneath his eyes, his temperature was 101° F., there was a certain amount of tenderness over the right side of the abdomen low down, but no distension worth mentioning and no swelling or thickening of any kind was perceptible. He was admitted in the afternoon and as he had just been shaken up in the course of his progress to the hospital I thought it wise, according to my usual custom, to wait a little while until the effects of the journey had passed off before attacking the case from an operative point of view, as seemed likely to have to be done I therefore left him with precise instructions that unless some distinct improvement took place in the course of the evening I should be sent for with a view to immediate operation. The boy's condition improved and there appeared to be no necessity for sending for me. On the following morning he seemed to my house surgeon to be still better and when I came to the hospital in the middle of the day I found him in this condition: the pain from which he had been suffering on the previous day had gone, the tenderness over the right side of the abdomen was less, there was no distension, the rigidity was very slight, and still no swelling of any sort could be found. His pulse was slower and there had been a very rapid drop in his temperature The temperature, instead of being 101° or something of that kind, had dropped to 97° since the time of my seeing him the day before, an interval of about 30 hours. He expressed himself as being altogether more comfortable and I was told, in point of fact, that the boy was clearly better and *in all respects more contented* than he had been on the previous day. But in spite of these apparent signs of improvement in the symptoms I came to the conclusion that the boy was suffering from an abscess of the appendix, probably gangrenous, and that an operation was immediately necessary. The first point I wish to impress upon you in connexion with this case is the fact that the boy was apparently improving so far as the ordinary observer could see although in reality he was steadily growing worse. I wish you more particularly to bear in mind the extraordinary decrease in the pain, the fall in the temperature, and the increase in the general comfort of the patient which had occurred in the course of the few hours since I had previously seen him. The apparent improvement was in my opinion entirely deceptive and I determined to operate, expecting, as I said at the time, to find a gangrenous appendix. My anticipation proved to be true; there was a perforation in the appendix which was sloughing at the point of its junction with the cæcum Around it was a stinking abscess and altogether the case was as bad a one of appendicitis as one could well meet with in a boy of the age I have mentioned. I removed the appendix and sewed up the resulting opening into the cæcum (the sloughing involved the cæcum itself), turning up a flap of peritoneum over it. The boy is doing very well.

In contrast with this case let us take that of another boy who came *into the Belgrave Ward on Oct 20th* with symptoms of appendicitis, which in his case had commenced on the 18th at midday with sudden onset of pain about the navel, gradually localising itself in the right iliac region, followed by sickness, diarrhœa, and so forth. When he arrived he had all the characteristic signs you would expect in such a case, a high temperature, and a flushed *face*. He had not the black marks under his eyes presented by the other boy, but that might have been accidental; there was some distension, with some slight tenderness and rigidity over the right iliac region, but no tumour or thickening could be felt; as a matter of fact, the condition was very much like that of the other boy. In those circumstances I left the same instructions as in the other case—viz, that unless a distinct improvement took place in this boy's condition aid was to be sought with a view to early operation. This patient, like the other, appeared to improve and no call was made for an immediate operation. He became more comfortable; his temperature, which when he came in was 101°, fell on the following morning to 99°. His pain was less, the distension had diminished, the tenderness on the right side was not very great, although it still existed; the rigidity was less and still there was no tumour.

These two cases at first sight appeared to be practically on all fours with one another. But in the second case, instead of at once proceeding to operation as in the first, because I felt that an abscess was present, I deferred the question of immediate operation, as I very much doubted the existence of any urgent disease in the appendix, my feeling being that whilst, as I have already said, the condition of things in the first case led me to anticipate grave trouble, in the second there was no need for hurry and that an early operation was altogether unnecessary.

Now comes the question, taking the fact that the cases seemed at first sight so very much alike, Why did I in the one case come to the conclusion, correctly, that there was grave disease with gangrene of the appendix, and why did I in the other case, which was so much like it, come to the conclusion that no disease sufficiently grave to call for early operation was present? This is a most important clinical question Had I been wrong in my determination in the second case it might have been a serious thing for the boy, and in the same way, if in the first case I had omitted to realise that the boy instead of getting better was getting worse, he would almost certainly have died, because if I had not operated when I did he would probably have been too bad for any operation to be of use. The whole position in those two cases depended upon two points—first, the condition of the temperature, and, secondly, the aspect and mental mood of the patient. I ought really to place the aspect of the patient first, because the state of the temperature is, although more obvious, a much less serious matter. The first boy when he came into the hospital, as I told you, had a flushed face, inclined to duskiness, black lines under his eyes, a furred tongue, and he looked distressed. He had not the "abdominal face" Do not be misled in these cases of appendicitis—we are not talking of other abdominal conditions—by the absence of what is called the abdominal face; it has little or no value in the early stages of appendicitis in young people But this aspect which I have mentioned—namely, the flushed and dusky cheek, the black lines under the eyes, combined with a very furred tongue, carry a very definite meaning. In the case of the first boy, you will remember that when I saw him on the second day, although he was altogether more comfortable, the pain, tenderness, and rigidity being less and there being still no sign of tumour or induration, the boy was dull, inert, contented, lying quite placidly in bed and saying he was better; all he wanted was to be left alone. In the case of the other boy, on the contrary, when seen on the second occasion the flushing of the face, although still present, was much less, his tongue had cleaned a little, and instead of lying in bed, dull and inert, he was sharper than he was the day before and answered questions much more quickly, smiling at something which was said to him. Later he soon lost the abnormal aspect of face altogether and became very sharp indeed, in point of fact he began to have some fear of operation and became nervous in consequence. Now, the difference in the changes in the condition of these two boys was what settled me in my diagnosis and so determined my line of treatment. The comfort of the first boy was simply due to inertia and dulled sensations resulting from increasing septic intoxication. He did not feel pain because he was indifferent; his blood was getting more and more poisoned from the absorption of septic material and he was growing more and more indifferent as the hours passed by. The worse that boy became the more contented he would be in consequence of increasing indifference resulting from septic intoxication which ensues very rapidly in cases of gangrenous appendicitis especially in young people. On the other hand, in a case like that of the second boy, as the inflammatory changes about the appendix begin to clear up the tendency to blood poisoning present at the time of admission gradually disappears and so instead of being abnormally content he becomes more alert, more active in mind, noticing things more generally, and by degrees returns to the condition of the normal individual. The lessons to be learned from these cases are of great value. Do not allow yourselves to be led to think that decrease of pain in a patient who is the subject of septic trouble necessarily means real improvement unless there is at the same time a general constitutional betterment, because, as I have tried to show, the decrease of pain may be the outcome of increasing septic intoxication, the disease being progressive all the time. On the other hand, if a general improvement in the condition of the patient is coincident with, or immediately succeeds, the loss of pain you may be sure that your way is clear.

Another point in these cases which must be carefully considered is the temperature. One is not infrequently told in cases of this sort upon going to see the patient perhaps for the second time that there is great improvement, because the temperature has fallen a couple of degrees in the course of the previous few hours. Now, whenever you have a patient suffering from this condition who has, let us say, when first seen a temperature of 102° F., which falls very rapidly to 99° or it may be to below the normal, bear in mind that this sudden fall may be a danger signal and not a sign that the patient is getting better. One of the commonest precursors of gangrene in this type of case is a sudden or very rapid drop in the temperature. A gradual fall in the temperature is always good, for it almost invariably indicates improvement. From what I have said you will see how easy it may be for inexperienced people to be deceived in cases of the kind which we are discussing; indeed, the symptoms are at times confusing enough to mislead those whose experience is considerable. A striking instance occurred in my practice not long since. A grave case of appendicitis was seen in a patient, 14 years old, late at night and an operation was arranged for the following morning. On arriving in due course for the purpose of operating I was met with the apparently gratifying report that there was great improvement, the patient, it was stated, being altogether better; the pain had almost gone, the temperature had fallen to normal, the child was dozing comfortably, a thing she had not done since the commencement of her illness, and it was hoped that the operation might be postponed. Upon examining the patient, however, I found that the falling to sleep was due to the septic intoxication, the comfort was the indifference resulting from the same cause, and the sudden drop of temperature was, I felt sure, due to gangrene of the appendix. My expectations about the case were fully realised, for I found at the operation, which was, of course, proceeded with at once, a gangrenous appendix in a stinking abscess. The patient fortunately survives, but the case was one of the worst I have seen to be followed by recovery.

To-day I have operated upon another case which teaches the same lesson. The patient is older than those already mentioned; he is 20 years of age and so is within the developmental period of life, which is an important point. A week ago he was seized with symptoms of appendicitis of the ordinary type—pain in the usual region, vomiting, and all the signs which attach to the complaint. He came into the hospital 48 hours ago. I was not sent for at once but saw him the day after his admission—that is to say, yesterday. He was then lying pretty comfortably in bed, his pain was less than when he came in, and I was told that his general condition had somewhat improved since his admission. Locally there were slight rigidity and a suspicion only of deep swelling. An operation was clearly indicated but as permission to operate had not been obtained it was postponed. This morning when I came to the hospital I learned that he seemed much better, was free from pain and comfortable, and the temperature had fallen. On seeing the man I did not like his aspect; there was the dusky flush on the face which I have mentioned, a black line under the eyes was very manifest, the tongue was thickly coated, and the breath was foul, still he was perfectly comfortable and happy. Here, again, operation revealed a gangrenous appendix, or rather the remains of it, in a stinking abscess. The same sequence of events had happened as in the other cases—diminution of pain, increasing comfort, and falling temperature, the apparent improvement, although the patient was rapidly becoming worse, being due to the deceptive indications of septic intoxication. Here also there was a rather sudden drop in temperature, which, let me once more impress upon you should be regarded critically in these cases as it may be a danger signal.

Now comes the question, Why in cases of this type—cases occurring in young growing subjects—are the symptoms so acute and yet so deceptive, because this particular type of appendicitis, so far as I know, occurs with comparative rarity in any but young growing subjects. In all young subjects, and the younger the patient the more accurately does the observation apply, the infective processes are very acute and the results of them are, as a rule, very destructive. A very slight septic irritation, for example, of a lymphatic gland in an infant will cause immediate suppuration of such violence that the whole gland may be completely destroyed in a very short time, a sort of thing which does not occur in an adult. In any part, therefore where the lymphoid tissue is very abundant, as it is about the appendix, the end of which is extraordinarily well provided with adenoid tissue, you may be sure that in young and growing subjects any destructive process will often be extraordinarily acute, a fact which partly explains the peculiarity of these cases in the young. The initial changes coming on acutely in the first stage are followed so rapidly by necrosis and decomposition that the commencement of septic intoxication begins almost, as it were, before the constitution of the patient realises the onset of the condition—in fact, at a point before the actual acute symptoms develop in an adult the patient if a young subject is becoming dull and listless from the effects of the rapid absorption of septic material by the superabundant lymphoid tissue. The peculiarity of the symptoms then in young growing subjects depends first upon the tendency to great activity in these destructive processes, and, secondly, to the rapid absorption of septic matter in a region supplied only too lavishly (for conditions of disease) with ready means of taking up septic material.

A very important question with regard to appendicitis in young people frequently arises in connexion with which it is sometimes extremely difficult to know how to act. All boys under a certain age, I need hardly say, are liable to attacks of what is commonly called "stomach ache." That is a common discomfort of early youth and as a rule the explanation is simple enough. These frequently occurring stomach-aches in large communities of boys—such, for an example, as may be found in an ordinary public school—often afford very difficult problems for the medical officers of institutions of that kind. Schoolboys are naturally prone (as are also, it must be admitted, many of their seniors) to suffer from "stomach-ache" the result of ill advised consumption of indigestible material. Such stomach-aches are either merely the result of acute indigestion or they may be abdominal pains resulting from appendix trouble. I was talking only a few days ago to a medical officer at one of the public schools in which a boy had recently become very rapidly ill from appendicitis and died, and he pointed out how nearly impossible it was to prevent a misfortune like this sometimes occurring, seeing that the amount of stomach ache always prevalent at the school was so great. If every case of stomach-ache that occurred were to be regarded seriously half the school would be generally in bed. On the other hand, if these abdominal pains are regarded too lightly from time to time there must occur one of these terrible cases of appendicitis which end so disastrously. And the difficulty is a real one, especially as the masters are, speaking generally, very averse to minor ailments being regarded too seriously In these circumstances it is worth asking the question whether it is possible to form any idea at all as to which of these attacks of abdominal pain are simple "indigestion" stomach aches and which are connected with some defect or disease about the appendix It is a very important point—much more important than it appears at first sight And I think *after having seen a very large number of these cases* in all sorts of conditions and in varying circumstances that it is at first possible to determine roughly between the ordinary colicky stomach ache in young subjects and similar pains which arise from disease in the appendix. Speaking generally you will find that the common stomach-ache—which is, of course, acute as a rule and subsides very rapidly, perhaps with an attack of diarrhœa or vomiting or perhaps without—is rarely associated with anything like a material rise of temperature and in passing off it does so at once and is done with. *There* is no sort of after thought with the ordinary stomach ache of which we are speaking now. Moreover, and this is an important point, in the ordinary stomach-ache the pain is general and *rather* tends as the attack is passing off to lean to the left side of the abdomen as the colon becomes concerned Now, the ordinary abdominal discomfort, call it stomach ache if you like, which is associated with appendical trouble is almost always, in the first instance, accompanied by a marked rise of temperature, it very rarely passes off at once to be completely done with, there is generally an after-thought of pain about these cases where the appendix is at the bottom of the trouble, and then the intensity of the pain in them, instead of tending finally to the left side of the abdomen, invariably inclines to concentrate itself somewhere about the right side, not necessarily over the right iliac fossa but on the right side of the abdomen It may expend itself over the region of the gall-bladder and I have seen it end in what at first sight looked like an acute attack of pleurisy After the passing away of the acute abdominal pain or discomfort in cases of "stomach ache" there is one sign which is as certainly pathognomonic of appendix trouble as *any one sign can be of a lesion, and that is* a feeling of discomfort or "stiffness" about the right iliac region upon attempts at extreme extension ("stretching") of the lower limbs, a condition which never follows mere "stomach ache", but in this connexion let me remind you of what I am constantly endeavouring to emphasise in these lectures—viz, that no one sign must be regarded as a sure indication of any given disease unless it is corroborated by *some of the other ordinary signs* of the complaint

A Clinical Lecture

ON

HALLUCINATION.

Delivered at the Richmond Asylum on Jan 6th, 1903,

BY CONOLLY NORMAN, F.R.C.P. IREL,

RESIDENT MEDICAL SUPERINTENDENT, RICHMOND DISTRICT ASYLUM,
DUBLIN

LADIES AND GENTLEMEN,—In a case of what it is convenient to call mental disease the whole mind is affected and divisions according to the various functions which appear to be engaged are merely divisions for convenience of study. One of the most striking symptoms of alienation is the existence of hallucinations The hallucinatory state is interesting on account of its frequency *and also because* sensory phenomena are, comparatively speaking, more easy to study than certain other mental conditions Furthermore, certain sensory disturbances which seem identical with, or closely akin to, hallucination occasionally occur, perhaps physiologically and certainly in conditions which are not commonly classed as mental diseases Finally, in the present state of our knowledge hallucination *appears* to be a relatively simple if not an elementary mental disturbance; therefore the hope is suggested that its study may furnish a key with which to open the more intimate chambers of the mind, for the progress of knowledge in other departments has usually been from the more simple to the more complex Thus while we must *recognise that* the occurrence of hallucination is not to be regarded as an isolated phenomenon in any case of insanity it is instructive to devote some special consideration to its clinical study.

It is in cases of paranoia that we find hallucination in its most remarkable form. Paranoia, as I have told you, is a condition characterised by fixed systematised delusion and, as is commonly said, an indifferent emotional state—that is to say, an *emotional state not constantly or fundamentally* exalted or depressed I am disposed to think that it would be more true to say that suspicion is the emotional element in paranoia Hallucinations are specially frequent in this affection and are commonly very constant in their mode of appearance In dealing recently with the question of incoherence I have pointed out to you that incoherence (perhaps sometimes true but often merely apparent) occurs in association with delusion It is, nevertheless, a less prominent feature of paranoia than of almost any other form of mental disease and its relative slightness facilitates the observation of sense disturbances

The case which I bring before you to day is one which exhibits hallucinations of almost every division of every sense When we speak to him we are reminded of Ball's striking remark to the effect that such cases recall to our mind the fundamental principle of the religion of Buddha—namely, that our senses are absolutely deceptive, that we are surrounded by void space, and that the whole universe is only a gigantic hallucination

The patient, a male, was admitted to the Richmond District Asylum, Dublin, in July, 1898 He was then aged 54 years He is married and is the father of several grown up children and was formerly employed as a butler His friends stated that he had been at least two years insane He was admitted from a workhouse, where he had been living for some time, having been thrown out of employment by his mental state. His family history is not very full. A maternal aunt suffered from senile dementia His mother was liable to asthma from middle age and "would not take any medicine for fear that there might be mercury" therein *The patient himself* was a steady hard drinker for many years. He is, as you will see, a calm, grave mannered man who expresses himself in measured and generally accurate language He rarely contradicts himself and seldom exhibits verbal incoherence His memory is excellent for everything connected with his own case and if he sometimes shows an indifference to current events this seems explicable through his absorption in his own troubles He is industrious *and a most intelligent worker* Since he has been in the asylum he has learned to weave extremely well; latterly he has given up that occupation which he thought did not suit him, and employs himself about the kitchen, where he is most useful He is never violent in action and his complaints, if one accepts his premisses, are not unreasonable, they are not rudely made or unduly pressed While at his work he often swears loudly and with apparent anger *at his imaginary persecutors* We do not find him a dangerous person though he belongs to a class in which are included some of the most dangerous of patients He sleeps badly He is apt to be noisy at night, loudly scolding his enemies, and sometimes getting up to search for them or their machines He tells a very definite story On July 22nd or 23rd, 1896, he was working in his pantry when a man whom he did not know came into the room *There is a slight discrepancy between the account* which he gave of this interview on admission and his account to day He then told us that he interchanged a few words with this man, now he says that they did not speak The stranger went out again and the patient, who took him to be a friend of one of his fellow servants, thought no more of the matter then That night, he tells us, he was attacked with pains in various parts of his body and at the same time heard a voice which *he knew was the stranger's using injurious* and abusive language From that time till now he has been constantly subjected to a variety of torments which he designates under the general name of "practice"[1]

It is not generally desirable to examine a patient with open reference to a systematic scheme, but this case is so full that much time would be lost in going over individually the various statements which he has made at different dates and as it happens one can examine his senses one by one without producing resentment or reticence on his part. Allow him from time to time to digress into theoretical explanations of his sufferings and denunciations of the practice to which he is subjected, and he readily tells everything. We find, then, hallucinations in the following sensory fields.

---

[1] The term I think, is not a
patients before who used it in
survival in this district of an c

1. *Dolorific.*—General surface sensibility is painfully affected. The pain has the character common in such cases. He describes it as "darts," "prods," "electric darts," "electric fire," "numbness darting along the limbs," "like a prod with a sharp instrument," and "as if one were struck with a lance." Sometimes the pain takes the form of "pressure," sometimes again, especially "when it comes on the breech it is like the stinging of a bunch of nettles." On one occasion he described a darting pain in the position of the ulnar nerve at the elbow which shot down the inside of the forearm and made the ring and little finger numb, but his pains rarely follow the course of a nerve. He sometimes has darts in his feet but mostly a burning pain in the soles. He so repeatedly talks of being "struck" with pain that I think this word does not merely express a theory but signifies also the sharp sudden way in which the pain comes. The pains were at one time described as being equally distributed everywhere. More recently they affect chiefly the left side.

2 *Kinetic or muscular.*—He experiences sensations of weight and heaviness in the limbs so that he feels that to walk or to raise his hand to his head requires an immense effort. He complains further of feelings of pressure, but it does not seem possible to disentangle these from sensations of pain

3. *Thermal.*—Besides sensations of pain which he compares to fire he experiences feelings of warmth "shot over" him as he says. These are followed by feelings of icy cold or the latter occur alone. These alterations in the temperature sense are a frequent cause of spontaneous and bitter complaints.

4. *Hygric.*—Baillarger, I think, was the first who described as a sense disturbance the subjective sensation of moisture Remadier in 1888 claimed that the sense of moisture constituted a special division of sense. Tambroni about ten years ago and more recently (September, 1902) Ravenna and Montagnini describe hallucinations of what they term the hygric sense Our patient tells you that he experiences feelings as if he was drenched with water. "I am drenched all over with water, or one side or the other is drenched with water. My clothes are not wet but I feel the water." At other times, however, he says he feels his bedding damp. There is also a sensation, not so frequent as the drenching, as if someone was dropping water upon him.

5. *Tactile.*—True tactile hallucinations are indicated by "a wet sticky feeling that they put into the ends of my fingers, though my fingers are not wet at the same time"; perhaps also by the occasional feeling of a sticky liquid covering the body all over.

6. *Genital.*—His "private parts are tampered with." Not merely pain is produced but specific sexual sensations occur, often ending in complete sexual orgasm. One of his strongest complaints is of this method of persecution which he describes as cowardly and vile.

7. *Visceral.*—There is a group of sensations connected with the abdominal viscera which in health rarely ascend above the threshold of consciousness but which often form portion of the hallucinatory field in insanity. It is convenient to call them visceral for want of a better name. The present patient is from time to time "struck" in the abdomen (interiorly) with rending pains. He has pains in the lower bowel as if the rectum was being torn out: "The rectum is being continually attacked with electricity"; pain in the upper part of the abdomen which "drives the stomach up into the chest"; an odd sensation, "as if I were hollow and saliva were dropping down from the throat into the stomach," perhaps belongs to the same order.

8. *Respiratory.*—I believe that there are specific sensations connected with the function of respiration, though the fact has not been generally recognised. This patient's breathing is "tampered with": "It strikes me on the chest when I am taking a breath so that I cannot breathe."

9. *Olfactory.*—Besides direct interference with the breathing there is an interference by noxious gases which at once suffocate and stink (the association, as might be expected, is very common). Sometimes the smell is mild, sometimes it resembles ordinary coal gas; at other times, without suffocation, there come horrible smells (fæces and the like). Of late olfactory disturbances are less complained of and the smells are only spoken of to-day as a reminiscence.

10. *Gustatory.*—In searching for these you must not confound taste and smell, as your patient generally does. In the case before us true gustatory disturbance occurs: the patient experiences strong tastes, always disagreeable, sometimes bitter, sometimes acid, sometimes salt "like brine."

11. *Visual.*—Séglas has divided visual hallucinations into three classes, elementary, common, and verbal. Our patient suffers mainly from the first. "Visions are cast before me; I am made to see a sort of green cloud, also landscapes and avenues of trees." The green cloud has been an early symptom. "Lights are flashed across the face when the eyes are closed; it is as if the eyelids were transparent." In reading "something flashes across the letters." Sometimes, he has told us, he sees the figure or the shadow of his tormentor, but when he strives to look at it intently it is gone. It is to be observed that the visual impressions have the air of being less distinct than the other hallucinations and this is what we most frequently find in such cases. On the other hand, the man who visited our patient in his pantry, whom he associates with the origin of all his troubles, was seen distinctly enough and is not at all regarded as being a "vision." However, we have no means of being sure of the objective unreality of this visitor.

12 *Auditory.*—Again adopting Séglas's division, which has a much more useful application to auditory than to visual hallucinations, we find that in the patient before us there are two classes, elementary and verbal. The former are represented by vague buzzing noises, also by a sound resembling a drum-beat, which he exemplified by tapping with his finger on the antitragus and saying, "It is like the sound thus produced." The verbal hallucinations, however—"the voices"—are the chief thing. When one asks whose the voices are he often replies that there is only one voice and that he recognises that as the voice of the visitor so often referred to, but he often talks of the "voices" much as other patients of his class do and speaks of the originators of the voice as "they." The voice can be briefly described in his own words: it is "personal, threatening, indecent, and blasphemous." You will find in most cases of auditory hallucination that the voices have these characteristics. Remarks are made to him about trivial events of his daily life; threats are uttered of murder, torture, &c.; horrid obscenity is dinned into him mixed with monstrous blasphemy. Sometimes he speaks of it as the "torturing voice" but more commonly as the "thwarting voice," because everything that it speaks is intended to vex, to annoy, and to thwart him. His belief in the reality of the voice is most intense. He often answers it in angry tones He laughs scornfully at any suggestion that it comes from his own mind. "The voice," he says, "whatever it may be, is a distinct voice. It comes to me as your voice comes now from you to me. It is equally loud, it is equally clear, it is equally real; I know it is not I that do it."

13 *Psycho motor* —Though the leading feature of this case is the occurrence of auditory hallucinations—i.e., hallucinations which appear in consciousness as manifestations of activity in the auditory speech centre—yet there are indications of the engagement of the motor speech centre. Thus he tells us: "By day I hear the voices through my ears the way I hear you speak; by night they are mostly working on the breath going in and out of the mouth." You will remember many cases in which I have recently demonstrated this condition to you in a much more marked degree and you will recognise the identity of the state he describes with the more extreme forms in which the "voice" is spoken of as originating in the patient's own vocal organs solely and being indeed not so much a voice as a sensation of movement

There is but one important hallucinatory group which seems to me to be absent in this case. The patient sometimes complains that he feels tired and stupid from annoyance but he never complains, as many paranoiacs do, that his mental operations are interfered with His thoughts are not compelled; he is not made to say or to do things against his will I believe that there is among our sensations a sense of mental action. Rarely in health does it appear above the level of consciousness, but in conditions of mental disease it is often very prominent, presenting what appear to be identical with, or at least closely analogous to, hallucinations. I am therefore in the habit of talking of hallucinations of the sense of mental action and I have demonstrated to you in several other cases what I mean by this phrase. The present case, so complete otherwise, does not exhibit any sign of this condition.

Association of hallucinations.—The commonest form in which association of hallucination of various senses occurs is that in which the patient sees a man or angel or demon who speaks to him. Here there is another association. He tells us: "When I am attacked with pain the voices come—never the one without the other." This is nearly identical with what he said to me more than four years ago: "The practice does not come without the torturing voices nor the voice without the torture." This fact confirms him in his intense belief in the reality and external nature of all his troubles. "It would be," he has said, "a queer mind and body that would torture anyone in this manner of its own accord." As I have said, it is not generally a good plan to examine a patient from notes as we have examined this man, but everything that he has now said he has spontaneously stated before in almost the same words either to me or to some of my colleagues.[2] His examination now has been based upon notes made from his own statements.

Time does not permit me to dwell to-day on the theoretical aspects of hallucination but two things may be remarked. Such a case as this shows clearly that whatever may be the remoter origin of hallucinations the sensory centres in which in health we receive impressions from without must be engaged in disease. No force of imagination would enable our patient to conceive so complete a series of sensations involving almost every variety of every sense and distinguishing from one another with physiological accuracy various sensory fields of the existence of which he must have been intellectually perfectly ignorant.

The true essential condition of mental disease in this man appears to me to be found not in his hallucinations, picturesque and remarkable as they are, but in the fact that the judgment is so far impaired that it accepts the hallucinations. It is not merely the case that the patient is deceived by a wrongly acting sensory apparatus, but though he talks with considerable acuteness and reasons in a pseudo-logical way, yet he unhesitatingly accepts the absurd notion that all the complicated, protracted, and virtually incessant sufferings that he endures are due to the machinations of a man whom he never saw but once and for whose action he can suggest no motive. Therefore, either the sensory centres must directly take part in the function of reasoning or else the higher psychical centres are affected with the same disease which disturbs the former. In either case the solidarity of cerebral function is complete.

ON HOUR-GLASS STOMACH FROM A PERSONAL EXPERIENCE OF 28 OPERATIONS.

By A. W. MAYO ROBSON, F.R.C.S. ENG.,
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THOUGH hour-glass stomach may arise from three separate causes—chronic gastric ulcer, perigastritis due to adhesions, and cancer—the deformity in itself almost constitutes a distinct disease which is associated with a peculiar train of symptoms. The name "hour-glass stomach" was adopted long ago when the disease was always thought to be congenital and before it was recognised that the stomach might be divided into more than two cavities, and the name is sufficiently distinctive to hold its own in medical literature.

The cases given below so distinctly prove that hour-glass stomach owes its origin to definite organic disease that I need not spend time over combating the question as to whether it is always acquired, for doubtless very rarely it may occur as a congenital condition, just as congenital narrowing may be found at the pylorus, in the intestine, or in the rectum. As yet, however, in an experience of over 1000 operations on the upper abdomen, in which the stomach could be seen and examined and about 400 of which have been on the stomach itself, I have not met with a single case of congenital hour-glass constriction.

Perigastric adhesions may cause a narrowing of the stomach in two ways as exemplified by Cases 1, 2, 16, and 19 related hereafter. In Case 1 perforation had led to firm adhesions to the anterior abdominal wall, and ulceration had led to cicatricial contraction. In Case 2 the stomach was divided into three portions, the proximal narrowing being dependent on a band of adhesions extending from the liver to the transverse colon, and the distal constriction being caused by cicatrisation of a chronic ulcer. The first cavity was divided into two by the firm band, leaving the middle loculus of the stomach the smallest of the three cavities and the cardiac pouch the largest. In Case 16 the perigastritis had led to adhesions of the anterior wall of the stomach to the anterior abdominal wall, thus leading to a sagging of the lower wall of the stomach on each side of the adhesion, so that when the patient was erect the food had to be forced upwards from the first cavity into the second and then from it through the pyloric orifice. In this case the patient was quite comfortable so long as she was lying down and taking her meals in that way, but feeding in the erect posture produced great distress. Case 19 is another example of perigastritis fixing the stomach to the anterior abdominal wall, but as in Case 1 the ulceration had also produced a cicatricial stenosis of the centre of the stomach so that two causes were at work in producing the hour-glass deformity. With the exception of the four operations for cancerous hour glass contraction, in all the others the deformity was due to chronic ulceration.

The symptoms for a time entirely depend on the cause, whether that be ulcer, cancer, or perigastritis, but ultimately when the deformity has developed the signs are more or less distinct. While in nearly all cases the cause has been capable of diagnosis, the effect has also been diagnosed in some and may be in nearly all cases if care and time be given to the diagnosis.

It is unnecessary here to enter into the ordinary symptoms of ulcer or of cancer. In the latter the history will have been an acute one and associated with a well-marked tumour of the stomach, the symptoms being referable rather to the disease than to the deformity, but in the former (ulcer) in all the patients that I have seen there has been a long history, in some cases extending over 20 years and in no case under two or three years The symptoms are for the most part pain after food, vomiting, sometimes of blood, and great wasting. In a number of cases tumour develops owing to the enormous thickening which occurs around a chronic ulcer, and so marked has this tumour occasionally been that some of my patients have been sent with the idea that they had cancer and even when the abdomen has been opened it is not always easy to say that the case is simple and not malignant. The well-known fact that cancer not infrequently supervenes on chronic ulcer adds to the difficulty, but when the abdomen is opened it will be found as a rule that the glands in ulcer are discrete and rounded and the tumour is not nodular or craggy, nor are any secondary nodules seen on the surface of the stomach or in the liver; moreover, ascites is absent. As a rule, dilatation of the proximal pouch, when the cause is ulcer, leads to symptoms simulating dilatation from pyloric stenosis. In several of my cases the patients have been conscious of fluid passing from one cavity to the other with an audible gurgle or murmur, and in one case, with the stethoscope over the epigastrium, I was able to hear the passage of the stomach contents through the strictured part, on alternately compressing each side of the abdomen. In several cases, on distending the stomach with carbon dioxide, the proximal cavity first became distended and afterwards both cavities became outlined with a sulcus between. Another distinctive sign is the following. On washing out the stomach until the fluid returns clear, suddenly, without any warning, the next lavage immediately afterwards may return foul owing to the second cavity having regurgitated its contents into the proximal clean one; or as in Case 6, the second cavity discharges foul material by the side of the tube which has the moment before been evacuating clear fluid. A sign pointed out by Wolfler is that on washing out the stomach the fluid may entirely disappear and cannot be made to return through the tube, the reason being that it has passed straight through into the second pouch.

The distinctive symptoms will depend on the position of the constriction. In Case 15 the narrowing was close to the cardiac orifice and the first cavity consisted mainly of the dome of the stomach. Here, the fluid, directly it entered the stomach, passed over the ulcerated surface and produced pain almost immediately after swallowing. It will be easily seen that the constriction in this position may simulate stricture of the œsophagus; the differential diagnosis may, however, sometimes be made by the passage of an œsophageal bougie. In the greater number of my cases the constriction has been about four inches from the pylorus and in nearly all the proximal cavity has been larger, giving rise to the well-known symptom of dilatation of the stomach due to pyloric stenosis. In nearly all cases of hour-glass stomach spasm of the pylorus is present, since the ulcer is usually associated with hyperchlorhydria and with considerable irritation, in which cases the second cavity may be dilated so as to equal the first in size, or there may be also cicatricial stenosis of the pylorus, as in Case 6, where at the same time pyloroplasty and gastroplasty were performed. Very frequently, however, the second cavity is of minor importance and in such cases hour-glass stomach is usually not diagnosed, the operation being simply undertaken for chronic gastric ulcer with dilated stomach.

---

[2] I am indebted for many valuable notes on this case to my former colleagues Dr. D. F. Rambaut, Dr. W. J. McKeown, and Lieutenant G. F. Sheehan, R.A.M.C., and to my present colleague, Mr. J. M. Redington.

The treatment of this condition is purely surgical and, in fact, operation ought to be undertaken long before the ulceration has led to such extreme deformity, for during the whole of the intervening period life has been in jeopardy, either from perforation or hæmorrhage, and during the whole of the time the patient has led a miserable existence on the verge of starvation because of the inability to take proper or sufficient food. After surgical treatment has been decided on the nature of the operation will have to be settled when the abdomen is opened and the stomach is exposed Where the narrowing is in the centre of the stomach, gastroplasty is a most efficient procedure and in all the cases in which I have performed that operation alone the patients have recovered and have remained healthy. In Case 6, where at the same time I had to perform a double operation, gastroplasty and pyloroplasty, I had to apply the sutures under tension owing to the length of the stricture. Had I been operating now I should have performed a gastro-gastrostomy together with a gastro-enterostomy which would probably have given a good result.

The operation of gastroplasty may be performed either by means of simple sutures or by suturing over the largest size bone bobbin, the latter being the method that I myself have adopted, the first principle to be borne in mind being to make the opening sufficiently large to secure union of the edges without tension. If the ulceration has not produced extreme contraction and the second pouch is not very prominent, a posterior gastro-enterostomy may be the operation of choice and it has answered quite well on the six occasions in which I have employed it, but my experience would lead me not to advise the anterior operation in these cases. Where the two cavities are equally dilated or connected by a very long stricture as in Case 6, an anastomosis may be made between the two cavities so as to short-circuit the stricture by the operation known as gastro-gastrostomy, but if there is active ulceration going on or the pylorus is stenosed, I would at the same time recommend a posterior gastro-enterostomy. Dr. Joseph A. Blake has recently suggested a modification of gastro gastrostomy after the method employed by Finney in pyloroplasty; the idea seems a useful one and has answered well in one case.

It is most important to make a very careful examination of the whole of the stomach in order to see that the proximal cavity is drained either into the distal one or into the jejunum, for it has happened on several occasions in reported cases that a gastro-enterostomy has been performed by joining the second cavity to the bowel, which can, of course, be of no benefit. In two reported cases the strictured passage has been digitally dilated on account of the difficulty in gaining access either because of extensive adhesions or from its position near the cardiac orifice, but in such cases it is desirable at the same time to perform a gastro-enterostomy.

In cases of cancer causing hour-glass contraction two procedures are open to the surgeon—either the performance of gastrectomy or gastro-enterostomy. In two of my cases the latter operation was done, the one being performed by the anterior method, where the patient died on the tenth day, and the other by the posterior method, the patient being extremely ill and unable to bear the major operation of gastrectomy which was done five weeks later with an excellent result. In the two cases where excision of the constriction was performed, the two ends of the stomach being united to a large decalcified bone bobbin as in enterectomy, the patients made smooth recoveries, one living for 16 months and the other being well at the present time, nearly three years later.

The following is a brief description of the cases to which I have referred.

SIMPLE HOUR-GLASS STOMACH.

CASE 1.—The patient, a married woman, aged 45 years, was admitted to the Leeds General Infirmary on May 10th, 1899, with a nine years' history of stomach trouble. The first attack was accompanied by severe pain after food and by vomiting so that she was unable for three weeks to retain anything on the stomach. After a period of almost complete starvation she recovered and was comparatively well for six years when a second period of illness occurred. On both occasions a swelling in the epigastrium with great tenderness was noticed. In September, 1898, a third attack occurred, since which time she had never been free from pain and the swelling and tenderness in the epigastrium had persisted. The patient was very much reduced in strength and weight.

An operation was performed on May 18th, 1899. Very firm adhesions were discovered between the anterior stomach wall and the parietes, on separating which a perforation was found in the centre of a cicatricial mass placed in the middle of the stomach which had divided the organ into two cavities, the proximal one being the larger. The stricture was divided longitudinally by a very free incision and the edges were brought together transversely over a decalcified bone bobbin. The patient was able to leave for home on June 6th when she weighed 6 stones 7 pounds, this being a gain in weight. On July 29th a report was received saying that she weighed 7 stones 2 pounds and that she was well.

CASE 2.—In May, 1899, I was asked by Dr. W. Duncan of Clay Cross to see a female patient, aged 26 years, who had been ill for 15 years with stomach symptoms, characterised by pain after food and vomiting. For some years the vomit was coffee-ground in character and streaked with bright blood. It varied from a small quantity to several pints, but for the past eight years no blood had been vomited, the vomit being sour, watery fluid in large quantities. Flesh had been steadily lost until the patient was reduced almost to the state of a living skeleton.

On June 6th on opening the abdomen the stomach was found to be trifid owing to a double constriction, the proximal one being formed by an adhesion passing from the liver across the greater curvature of the stomach, constricting it; the distal cavity was caused by a stricture about three and a half inches from the pylorus, it being dependent on a cicatricial contraction due to chronic ulcer. The proximal cavity was the most dilated and this gave rise to the stomach splash and to the well-marked signs of stomach dilatation. On dividing the firm band of adhesions forming the first constriction a sulcus was left in the stomach. On opening the second stricture a chronic ulcer was exposed and the channel was so narrow that it would only allow the passage of a No. 12 catheter. Gastroplasty was performed, one of the largest size decalcified bone bobbins being used. The patient made a good recovery and returned home within the month. A report received on August 6th stated that she had gained two stones in weight and was quite well.

CASE 3.—A married woman, aged 23 years, was admitted to the Leeds General Infirmary with a history of two years' pain after food and vomiting with great tenderness in the epigastrium and loss of three stones in weight during the past two years. A well-marked stomach splash could be made out but no tumour was manifest and the patient could with difficulty bear palpation on account of great tenderness.

On July 20th, 1899, the abdomen was opened and the stomach was found to be hour-glass in shape A constriction was found two inches from the pylorus, just admitting the tip of the little finger. Gastroplasty was performed, the suturing being carried out over the largest-sized bone bobbin. The patient made a good recovery from the operation and returned home on Sept. 16th.

CASE 4.—The patient, an unmarried woman, aged 46 years, was seen by me with Mr. F. T. Hindle of Askern. There had been indigestion and flatulency for 20 years and free hæmatemesis two years previously. There was great loss of flesh, dilatation of the stomach was well marked, and epigastric tenderness was present.

On July 28th, 1899, gastroplasty was performed. Extreme contraction one third of the stomach length from the pylorus was discovered. The stricture would just admit the tip of the little finger. The patient made a good recovery from the operation and there was an increase of weight on Nov. 1st. The patient was quite well a year later, but soon after she began to complain of pain dependent on perigastritis, for which an operation was subsequently performed (see Case 16).

CASE 5.—In August, 1899, I saw a female patient, aged 52 years, with Dr. E. Walker of Huddersfield. The patient gave a history of stomach trouble lasting for 26 years. At first the pain had occurred about two hours after food and vomiting was only occasional. During the first 20 years there had been periods of comparatively good health between the severe seizures. In 1894 she was told by an eminent physician that she would never be cured but might be relieved by dieting. For a year she had been sick every third day, vomiting in large quantities, and during that time she had lost two stones in weight, her weight being reduced to 5 stones 10 pounds in her clothes. Dilatation of the stomach was well marked; peristalsis could be seen and what was taken to be the pylorus could be felt to harden under the palpating hand.

On Sept. 9th the abdomen was explored and an hour-glass contraction of the centre of the stomach was discovered, the stricture only just admitting a No. 7 catheter. The proximal cavity of the stomach was enormously dilated and there were great thickening and induration around the stricture. Gastroplasty was performed by means of a bone bobbin and the patient made a good recovery. On Nov. 1st she had gained 26 pounds in weight, at Christmas she had gained four stones, and in December, 1903, I had a note to say that her digestion was perfect.

CASE 6.—The patient, a married woman, aged 36 years, was admitted to the Leeds General Infirmary on Sept. 28th, 1899, with a history that for ten years she had had stomach trouble, during which time she had lost three stones in weight. The symptoms had been intermittent but never completely absent during the whole of the time and for many months she had only been able to get relief after vomiting which occurred every day. The physical signs were very distinct and peristalsis was well marked and much increased by the use of the stomach-tube. When the stomach was washed out, after the first cavity had been thoroughly cleansed, the patient would suddenly retch and vomit a large quantity of foul material by the side of the tube, and as this contained no bile it clearly came from the second cavity. The second sign elicited was by filling the stomach with water, when the outline of the first cavity could be easily percussed. A third sign was found by filling the stomach with air, when the lower limit of the first cavity could be readily felt in the left hypochondrium; it became lost in the middle line and the stomach resonance could again be discovered to the right of the umbilicus. The stomach splash could always be elicited. Free hydrochloric acid was found in the stomach contents.

Operation was proceeded with on Oct. 5th. Numerous adhesions were found and detached between the stomach and abdominal wall, when two cavities were discovered separated by a long narrow isthmus two and a half inches in length, this being surrounded by dense cicatricial tissue. The pylorus was also much narrowed and thickened, it being also cicatricial. Gastroplasty was performed with some considerable difficulty on account of the great length of the stricture, and after this had been completed pyloroplasty was also carried out, but in neither case did I feel satisfied with the sutures, which were applied under tension. The patient was fairly comfortable after the operation and beyond a little regurgitation which was relieved by lavage on the third day no untoward symptoms followed, and a week later a note was made to say that the patient was doing well and altogether comfortable. At ten o'clock on the eighth day after operation she was suddenly seized with violent pain and the pulse rose to 120. In my absence Mr. R. Lawford Knaggs was summoned and after consultation with Mr. H. Littlewood it was decided to reopen the abdomen. The wound was found to be firmly healed, but on opening the peritoneal cavity air and bile-stained fluid escaped, due to perforation of the pylorus, some of the tense stitches having ulcerated through. Gastrorrhaphy was performed and the abdomen was washed out. Unfortunately, however, the shock was too great and the patient succumbed within a few hours.

CASE 7.—The patient, an unmarried woman, aged 27 years, whom I saw with Mr. E. Ellis of Halifax, gave a history of stomach symptoms lasting for eight years. There had been pain two hours after food and vomiting. A stone in weight had been lost in two years.

On March 21st, 1900, on opening the abdomen and exposing the stomach the latter was found to be hour glass in shape, owing to cicatricial stricture three inches from the pylorus just admitting the tip of the little finger. Gastroplasty was performed by means of a bone bobbin. The patient made a good recovery and later I had a report to say that she was well and was several pounds heavier than before the operation. On Dec. 19th, 1903, Mr. Ellis wrote to say that she was in good health, looked well, weighed nine stones, and was able to digest her food quite satisfactorily.

CASE 8.—The patient, an unmarried woman, aged 29 years, had suffered from chlorosis due to overwork for years before the beginning of her stomach troubles four years previously, since which time she had had pain after food and occasional vomiting with hæmatemesis and melæna. Very thorough medical treatment had been followed out on several occasions in the way of rest and rectal feeding but without any benefit. There had been great loss of flesh.

On opening the abdomen on March 22nd, 1900, omental adhesions were discovered, these covering a puckered ulcer on the front wall of the stomach three inches from the pylorus where there was an hour glass contraction which would just admit the tip of the little finger. Pyloroplasty was performed, a bone bobbin being used. The patient made a good recovery and returned home on April 30th. On May 9th she had gained several pounds in weight.

CASE 9.—The patient, a youth, aged 18 years, was seen on Feb. 24th, 1900, and gave the history that he had never been strong since an attack of pneumonia four years before and that he had had pain after food for two years, the pain usually coming on from one to one and a half hours after meals. Although close on six feet in height his weight was only 9 stones 8 pounds. He was not absolutely an invalid but he was unable to carry out any of his ordinary duties and was getting worse rather than better. The stomach was dilated, the lower border reaching midway between the umbilicus and the pubes. A stomach splash was very evident and there was well-marked tenderness over the pylorus. After two months' careful general treatment he had lost five pounds in weight and felt weaker.

Operation was performed on April 24th. Hour-glass contraction of the stomach was found four inches from the pylorus, there being a scar on the surface of the stomach at that point, showing that the cause was chronic ulcer. The stricture would only admit the tip of the little finger. Gastroplasty was therefore performed, the largest-sized bone bobbin being used. The patient made a good recovery from the operation but in November the stomach splash could easily be elicited as if the muscular power had not been regained. Lavage of the stomach and the administration of strychnine were advised. In December, 1903, I had a report to say that he was able to attend to his business every day, though he had still to take care in his diet and not to get over fatigued.

CASE 10.—The patient, a single woman, was seen with Dr L. A. Mackenzie of Bradford. She was in a state of great exhaustion with extreme emaciation, the history being that she had had symptoms of gastric ulcer for 15 years and that for six years she had lived on liquid food in small quantity. She had been for a long time completely bedridden.

At the operation (which was performed on April 30th, 1900) the stomach was found to be extensively ulcerated and scarred there being hour glass contraction four inches from the pylorus just admitting the tip of the little finger. At this point there were signs of an old perforation that had been covered by omentum which was extensively adherent. The stomach was so bound down by adhesions that anterior gastro-enterostomy only was possible. The patient rallied well from the operation and progressed satisfactorily up to the twelfth day, when after a good night she expressed herself as feeling very well. About midday she complained of abdominal pain, suddenly became collapsed, and died a few hours later apparently from perforation, though a necropsy could not be obtained to verify this.

CASE 11.—A man, aged 44 years, was admitted to the Leeds General Infirmary on May 31st, 1900. He gave a history of stomach trouble for 23 years with occasional periods of good health, though recently the healthy intervals had been very short. Coffee-ground vomiting was a marked symptom. There was considerable loss of weight.

Operation was performed on June 7th. A large cicatricial surface two inches in diameter was discovered on the front wall of the stomach, forming an hour-glass contraction from two and a half to three inches from the pylorus. On incising this longitudinally the mucous membrane was found to be ragged and ulcerated for two inches on either side of the incision. Gastroplasty was performed over a bone bobbin. In this case no free hydrochloric acid could be discovered in the stomach contents. The proximal cavity was the larger, the distal being comparatively small. The patient made a good recovery and returned home on July 25th.

Case 12.—Early in October, 1900, I was asked by Dr. T. B. Hearder of Ilkley to see a man, aged 52 years. There was a three years' history of pain and vomiting with epigastric tenderness and loss of flesh. On examination the stomach was found to be markedly dilated.

At the operation on Oct. 12th an hour-glass contraction was discovered near the centre of the stomach but the stricture was not extreme. Posterior gastro-enterostomy was performed and the patient made a good recovery. On March 4th, 1901, he wrote to say that he was quite well and that he had gained 1 stone 5 pounds in weight.

Case 13.—An unmarried woman, aged 25 years, was admitted into the Leeds General Infirmary on Nov. 5th, 1900, with a history of stomach symptoms and pain and vomiting for three years. During part of the time she had been in hospital and under thorough medical treatment but without material benefit except of a temporary character.

Operation was performed on Nov. 15th. A large constriction was found in the centre of the stomach forming a characteristic example of hour-glass contraction, both cavities being dilated and the proximal being larger than the distal cavity. Numerous adhesions had to be separated, especially around the pylorus, and others between the stomach and colon. A posterior gastro-enterostomy was performed from which the patient made an uninterrupted recovery. She returned home on Dec. 11th. On April 9th, 1901, she returned to the infirmary on account of having had some recurrence of pain and vomiting, but under rest and careful dieting the symptoms completely passed off in three weeks and she was sent home, weighing seven pounds more than she did when in the hospital on the former occasion. During the three weeks when under observation she had no sickness and during the latter part of the time she was able to take ordinary food without discomfort.

Case 14.—A man, aged 53 years, was admitted into the Leeds General Infirmary on Nov. 29th, 1900, with a two years' history of pain from an hour to one and a half hours after food. Vomiting was not a marked symptom until a few weeks before admission. His ordinary weight was 14 stones but on admission it was 10 stones 10 pounds. There were no signs of dilatation of the stomach and free hydrochloric acid was present.

At the operation on Dec. 6th an hour-glass contraction of the stomach was found three inches from the pylorus, there being considerable thickening of the stomach wall at that point; the proximal cavity was the larger. Posterior gastro-enterostomy was performed. He made a good recovery from the operation and returned home on Jan. 7th, 1901.

Case 15.—On Feb. 13th, 1901, an unmarried woman was sent to me by Dr. J. Mackenzie of Burnley with a history of stomach trouble extending over several years. The attacks had come on about four times a year, lasting from six to eight weeks, when after starvation with rectal feeding she was relieved for a time. The stomach reached to the level of the umbilicus but after distension with carbon dioxide the greater curvature was two and a half inches below. The stomach splash was still well marked four hours after a meal. On distension the outline of the stomach appeared to be bilocular, there being some irregularity in the centre. The patient was very thin and feeble.

Operation was performed on April 2nd. A cicatricial contraction of the body of the stomach was found within an inch of the cardiac orifice, the stricture extending obliquely across the stomach. In this case the cardiac complement formed the smaller sac, the distal pouch forming the bulk of the dilatation felt before operation. There was spasm but no stricture of the pylorus. Gastroplasty was performed and the patient made a good recovery from the operation.

Case 16.—The patient, a single woman, aged 49 years, who was seen with Mr. F. T. Hindle of Askern, had suffered from gastric symptoms for 20 years. Gastroplasty had been performed on July 28th, 1899, for hour-glass contraction, the constriction being at a point one-third of the stomach length from the pylorus. She had made a good recovery and had increased in weight so that at the end of the year she was quite well. Soon afterwards she began to complain of pain on movement and on straightening herself, as well as of discomfort and pain after meals, with flatulency, though she had not vomited. When she rested in bed she completely lost her symptoms and could take food well though directly she resumed the erect posture the pain recurred. There were tenderness and an indefinite swelling to the left of the middle line with a well-marked stomach splash on succussion. A diagnosis was made of perigastritis with adhesions to the anterior abdominal wall. After general treatment had been carried out for some time without any benefit operation was decided on.

On opening the abdomen on Jan. 24th, 1901, an old scar with a firm adhesion was found between the anterior stomach wall and the parietal peritoneum just above the umbilicus to the left. This firm adhesion produced little discomfort when the patient was recumbent, but when the body was erect it re-created the old hour-glass deformity with a difficulty in emptying the proximal pouch which was markedly dilated. The adhesion was separated and on invaginating the stomach wall so as to pass the fingers through the part that had been formerly stenosed the channel was found to have a wide calibre, so that the gastroplasty had been quite effective. It was found, however, that there was some narrowing of the pylorus though no absolute stenosis. A posterior gastro-enterostomy was therefore performed. The patient made an excellent recovery and left the surgical home at the end of three weeks. She was then five pounds heavier than at the time of operation and I had a report from Mr. Hindle on May 14th, 1903, to say that she was quite well in every respect.

Case 17.—The patient, a single woman, aged 29 years, was seen with Mr. M. Bryson of York. She had been ill with epigastric pain for ten years. The pain had been constant with exacerbations and had been increased after food, though this was not a marked symptom. She had never vomited blood but had passed blood freely from the bowel on several occasions. She said that all her trouble dated from an attack of typhoid fever ten years before. She was extremely weak and very thin, only weighing 6 stones 11 pounds with her clothes on. On examination just above the umbilicus there was a well-marked tender swelling that seemed to be bound down by adhesions. It was feared that the tumour might prove to be malignant.

The abdomen was opened on Oct. 24th, 1901, by an incision one inch to the right of the middle line above the umbilicus, when a large tumour was discovered in the centre of the stomach, there being a dilated portion of the stomach on each side of this. The communication between the two cavities was a small channel surrounded by an indurated chronic ulcer. The induration extended along the lesser curvature of the stomach, where enlarged glands were felt. There were many adhesions between the stomach, the liver, the gall-bladder, and the colon. Posterior gastro-enterostomy was performed. The patient made a good recovery and returned home. On Dec. 19th, 1903, I received a letter to say that she was quite well and that she had not had a bad symptom since her operation two years before.

Case 18.—The patient, a single woman, was seen with Dr. W. B. Mercer of Ripponden on account of wasting associated with pain after food and vomiting, the patient having had stomach symptoms for over two years. She was very thin, only weighing 5 stones 10 pounds, and was feeble and anæmic. The stomach was markedly dilated and there was a hard swelling in the centre of it. She had tried medical treatment very thoroughly for the greater part of the time since the first attack, but had never been long free from pain.

On March 7th, 1902, the abdomen was opened and an hour-glass stomach was found, with well-marked, hard, cicatricial tissue about the centre. As the narrowing of the channel was not extreme and the pylorus was patent a posterior gastro-enterostomy was done by connecting the first cavity of the stomach to the jejunum. The patient made a good recovery and when she left the surgical home had gained weight. After her return home there was some recurrence of pain, but she was able to resume her duties and when I heard later of her Dr. Mercer said that he had not seen much of her for the last two months. A subsequent report received in December, 1903, was to the effect that the patient had relapsed. From the history the recurrence of trouble is probably due to adhesions but the patient is unwilling to have anything more done.

CASE 19.—The patient, a married woman, aged 41 years, was seen with Dr. T. Robinson of Kensington. The patient gave a seven years' history of stomach trouble in the shape of painful indigestion, though after the first two years the symptoms had clearly pointed to gastric ulcer. She had been relieved by medical treatment up to 11 months ago, when there was a recurrence of pain after food with loss of flesh. At Christmas she had a free hæmatemesis and a second attack occurred a week later. On Jan. 7th, 1903, a swelling of the epigastrium could be felt of about the size of a walnut, it being moveable and tender. On May 18th a third attack of hæmorrhage occurred and from that time onwards she had been steadily losing flesh, so that her weight had diminished from 9 stones 4 pounds to 7 stones. When she was seen there was a well-marked tender tumour in the epigastrium. The patient was complaining of great weakness and she was profoundly anæmic. There was no ascites and the legs were not œdematous.

On Nov. 21st, 1903, the abdomen was explored through an incision to the right of the middle line above the epigastrium, when the stomach was found to be adherent at the front over an area of about the size of a five-shilling piece. On separating this a small aperture was discovered where perforation had occurred. The centre of the stomach was occupied by a hard cicatricial mass dividing the organ into two cavities. The index finger could be passed with difficulty from one cavity to the other. The glands along the lesser curvature were enlarged but discrete and other glands were found at the back of the stomach and in the great omentum. The proximal cavity was connected to the jejunum by posterior gastro-enterostomy, a bone bobbin being employed. On account of the great induration of the tissue surrounding the point of perforation it was impracticable to apply sutures. An omental graft was therefore detached from the great omentum and stitched into position so as to close in the perforation. Recovery was uninterrupted and the wound healed by first intention. She was able to take food from the first day and soon began to put on flesh When she left the nursing home on the twenty-fourth day she was looking well and expressed herself as feeling better than for two years. She had gained several pounds in weight and could eat anything in reason.

CANCEROUS HOUR GLASS STOMACH.

CASE 20—The patient, a married woman, aged 36 years, was sent to me by Dr. W. W. Chamberlain of Rawdon on Sept. 21st, 1900, and was admitted into the Leeds General Infirmary. There was a history of daily vomiting for four months and as the vomiting always occurred within an hour of meals the patient was reduced to the last degree of weakness. A tumour had recently appeared and was readily palpable on the right of the umbilicus. As she was so weak she was put on rectal feeding for a few days but without improvement and operation was decided on as a last resort.

Operation was performed on Sept. 28th. An annular cancer of the stomach was found three inches from the pylorus. It had considerably encroached on the lumen of the stomach, so that the stricture would barely admit the passage of the finger. The proximal cavity was very much dilated but the cavity between the growth and the pylorus was not dilated. An anterior gastro enterostomy was therefore performed as there were some extensive adhesions and it was thought that time might be saved by the anterior method. Regurgitant vomiting followed and persisted until the third day, bringing her almost to the verge of death. Food and stimulants were then given in large quantities and from that time there was no more trouble with vomiting, but on Oct. 7th (the ninth day) she became collapsed and died in the evening.

CASE 21.—The patient, a married woman, was sent to me by Mr. T. F. Forster of Dalton-in-Furness on Jan. 24th, 1901, with a moveable tumour in the epigastrium that had been noticed three weeks previously; there had been no vomiting, although indigestion, pain an hour after food, and loss of flesh and strength had been noticed since August, 1899. She weighed seven stones, having weighed eight stones or more previously to her illness. The tumour appeared to be of the size of a tennis ball, was free from tenderness, and could be made to move across the abdomen from one side of the umbilicus to the other. On distending the stomach with carbon dioxide it reached nearly to the pubes on the left side, but very little distension was noticed on the right beyond the tumour.

The patient was admitted to the Leeds General Infirmary, and on Jan. 31st on exposing the stomach a tumour was found involving the whole circumference a short distance from the pyloric end, so that between the pylorus and the tumour a small second stomach cavity existed, the dilatation being formed entirely by the cardiac complement. The tumour was completely excised and the distal and proximal cavities were united end to end over a bone bobbin. Glands were removed from the lesser and greater omentum. Recovery was uninterrupted and the patient left the hospital before the end of a month, having regained the weight lost during the week after operation with an additional pound. The tumour proved to be cancerous. A report was received in 1903 to say that the patient was in good health and well nourished.

CASE 22—A man, aged 62 years, was sent to me by Dr. James Gardner of Burnley suffering from a moveable tumour, thought to be cancer of the stomach, which had been noticed for a month but which had been preceded by stomach symptoms, chiefly pain after food and slight vomiting, for quite a year. There had latterly been some slight coffee-ground vomit but no large amount of blood had been brought up at any time. The tumour was not tender and could be pushed up under the left and moved over to the right costal margin. A stomach splash was well marked on the left of the tumour and on distending the stomach with carbon dioxide the lump was pushed over to the right. The vomit was acid from the presence of lactic acid, but no free hydrochloric acid could be found. Pylorectomy was advised and the patient was admitted to the Leeds General Infirmary, being then in an extremely weak condition.

Operation was performed on Nov. 15th, 1900. On opening the abdomen a mass of growth was found in the centre of the stomach, forming a ring of cancer and leaving a cavity on its proximal and distal sides, the cardiac cavity forming the dilated stomach where the splash on succussion was felt. Dr. D. Seaton, who was giving the anæsthetic, advised that the patient was too feeble to bear a prolonged operation and a colleague also confirmed the fact that the pulse could be barely felt at the wrist. A posterior gastro enterostomy was therefore only performed, a bone bobbin being employed. The patient soon rallied and made a good recovery, gaining flesh and weight and expressing himself as very well. For his further history see Case 23.

CASE 23.—The patient had gastro-enterostomy performed on Nov. 15th, 1900. He seemed to be so well and had gained strength so rapidly that it was felt desirable to give him the chance of cure by completely removing the growth, and after fully explaining to him his condition he gave consent.

Operation was proceeded with on Dec. 20th, 1900. The radical operation of removing the growth by partial gastrectomy was performed, about half of the stomach being removed in order to leave a wide margin of healthy tissue between the growth and the wound. Union was effected by suturing the cardiac and pyloric portions together over a bone bobbin, catgut being used for the mucous and celluloid thread for the serous sutures, the whole operation being completed within the hour. No glands were felt beyond the resected area. Recovery was uninterrupted and he returned home within the month, eating and enjoying food and having gained considerably in weight. He lived for 16 months and for nearly the whole of the time took his food well and until January, 1902, retained his normal weight.

It will be seen that there are 23 cases of which 19 were simple and four were malignant. Of the simple cases 11 were operated on by gastroplasty alone and all the patients recovered; one by gastroplasty and pyloroplasty combined, the patient dying, as did the one in whom anterior gastro-enterostomy was performed. Of the six patients treated by posterior gastro-enterostomy all recovered. Of the four cases of cancerous hour-glass stomach three patients recovered, two of the cases being treated by partial gastrectomy.

MR. M. I. FINUCANE, M.R.C.S. Eng., has been nominated by the St. George's, Hanover-square, board of guardians as one of its representatives on the Metropolitan Asylums Board.

OCHRONOSIS:

THE PIGMENTATION OF CARTILAGES, SCLEROTICS, AND SKIN IN ALKAPTONURIA.

BY WILLIAM OSLER, M.D. McGILL, F.R.C.P. LOND., F.R.S.,

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE, U.S.A.

HERETOFORE ochronosis has been a pathological curiosity; the two cases here reported in alkaptonuria show that it may have interesting clinical features.

In 1866 Virchow[1] described a remarkable blackening of the cartilages in the body of a man, aged 67 years, who had died from aneurysm. The colour was coal black (as shown in his figures), not ochre-coloured or yellow; but it was not ordinary melanosis, and recognising the unique character of the condition Virchow called it ochronosis. Years passed before a second case was described by Boström,[2] that of a woman, aged 44 years, who had died from strangulated umbilical hernia. The same ebony-black discolouration of the cartilages was present. Then in 1892 Hansemann[3] described a third case, the patient being a male, aged 41 years, with general œdema and aneurysm of the left ventricle. He had had melanuria for 18 years. In a recently issued number of the *Deutsches Archiv für Klinische Medicin* Langstein and Meyer state that the examination of long-kept urine shows that this was not a case of alkaptonuria. There was no reduction of copper and no homogentisic acid could be found. Heile[4] recorded the fourth and fifth cases, one being that of a woman, aged 36 years, who had died from peritonitis after ruptured tubal pregnancy, and the other that of a woman, aged 52 years, with chronic leg ulcer and mitral valve disease. The sixth case was reported by Hecker and Wolf.[5] The patient was a man, aged 73 years, with long-standing melanuria and chronic endocarditis. In the eyes on each side some three or four millimetres from the corneal border there were black spots on the sclerotics. The urine was sometimes normal in colour when passed and sometimes brownish. It became black on standing for a day or two. The darkening was present for 11 years but was not constant. Blood, bile-pigment, indican, pyrocatechin, and drug pigments were excluded. It is distinctly stated that the urine did not reduce copper. Hecker and Wolf came to the conclusion that the reactions were those of melanuria. Post mortem there was the ordinary ochronotic blackening of the cartilages, arteries, &c. I am indebted to Dr. A. Garrod for this abstract from the *Festschrift* of the Dresden Hospital and he states that it is pretty certain this was not a case of alkaptonuria. The seventh case is recorded by H. Albrecht,[6] to whom is due the credit of suggesting the association of the condition with alkaptonuria. In a man, aged 47 years, who had died from pulmonary tuberculosis, the urine was dark-coloured and reduced the sulphate of copper, but the presence of alkaptonuria was not proved, for no homogentisic acid was obtained from it. After a week in the hospital he died and the necropsy showed a general ochronosis. A point of special interest was the grey-blue colour of the inner part of the ears, as if due to dilated veins.

I am able to report two cases of ochronosis in alkaptonuria in which the condition could be recognised clinically by the deep pigmentation of the cartilages of the ears and of the sclerotics, and in one by a remarkable ebony-black discolouration of the skin of the nose and cheeks.

CASE 1.—A man, aged 57 years, consulted me on Jan. 16th, 1895, for diabetes and rapid action of the heart. He had been an active business man and a successful politician. I did not question the existence of diabetes, as during a prolonged residence in Europe he had been under the care of several eminent colleagues in Berlin, Paris, and London, one of whom had referred him to me. After repeated examinations Dr. Futcher determined that the copper-reducing substance was not glucose and the case formed the basis of his paper on alkaptonuria in the *New York Medical Journal* in 1898. I need not refer in any detail to the condition of the urine in this case other than to state that it is never black when passed but darkens after a few hours. At my first examination I was impressed by a remarkable appearance of the sclerotics which showed small V shaped areas of deep pigmentation near the cornea. I thought it might be the result of old hæmorrhages, but the patient said that the condition had gradually come on and that it had annoyed him at first but that he now thought nothing of it. There was also a slight pigmentation of the nose and on the cheeks which looked like very thickly set comedones. As he left the room my attention was directed to the deep blue colour of the inner surface of the ears. I have seen the patient at intervals during the past eight years and have taken an increased interest in the deepening pigmentation of his face, eyes, and ears. I searched the literature at intervals for an explanation but without avail and I consulted Dr. de Schweinitz and Dr. Harry Friedenwald with reference to the pigmentation of the sclerotics. It did not seem to conform with any of the reported cases of this rare condition. Lately the patient came under my care in the private ward of the Johns Hopkins Hospital for anæmia and a weak, irregular heart. The pigmentation has extended considerably in the past six years and is now as follows.

Sclerotics.—The exposed V shaped portions are of a deep black colour, not in the entire extent, as there are areas of normal colour. The staining is in the sclerotic coat, not in the conjunctiva, and it does not extend to the covered parts of the eyeballs. Of late years it has become much darker; there was a brownish tinge in places which has now almost disappeared. There is nothing special to be noticed about the other parts of the eyes. The tarsal cartilages are not affected.

Ears.—From behind and along the free border of the helix the skin looks normal but when looked at from inside there is a remarkable blue-black discolouration, exactly like that produced by dilated veins, as Albrecht remarked. It is deepest in the concha and extends along the antihelix but not to the helix. I did not recognise at first that the pigmentation was in the cartilage. In certain positions and when the light falls into the ears the colour at once attracts attention. It has extended and deepened in the past five years.

Face.—Over the nose and the cheeks, in very much the butterfly distribution of lupus erythematosus, the skin is of a coal-black colour. At his first visit I thought that it was an unusual distribution of very black comedones. The line over the nose is narrow but widens and passes to the cheeks and extends over the malar bones and along the zygomata. There is no thickening of the skin, which can be picked up easily. The colour is remarkable, quite unlike anything seen in the skin in the ordinary pigmentary changes, but at first glance rather suggesting powder marks. Where present it is uniform, not patchy. It is nowhere else on the skin but Dr. Futcher tells me that small black spots have begun to appear on the back of the hands. One of this patient's sons has alkaptonuria.

CASE 2.—The patient is a brother of the patient in Case 1, his age being 49 years. This was one of the first cases of alkaptonuria described in the United States of America. He had applied for life insurance and had been rejected repeatedly. Dr. Marshall, of the University of Pennsylvania, studied the urine carefully and called the new copper-reducing substance glycosuric acid. The man remained quite well after he had got over his fright about diabetes. When the first patient was in the hospital this brother visited him frequently, and what was my surprise to find that he too had pigmented sclerotics and ears. The patches in the eyes were small, two vertically placed bands about five millimetres from the corneo sclerotic junction. They resembled in size and appearance those in his brother's eyes when I first saw him in 1895. The blue black colour in the ears, not nearly so marked as in Case 1, was confined to the fossæ and could not be seen from behind. The skin was normal, but through it appeared this remarkable leaden colour as though there was a diffuse nævus. The patient had noticed the pigmentation for several years. He was morbidly sensitive about it and it was with the greatest difficulty that I could induce him to come to the clinical laboratory where Dr. Emerson determined the persistence of the alkaptonuria. This patient died in April, 1903, from pneumonia after an illness of a few days. There was no post-mortem examination.

[5] Festschrift, Dresden Hospital, 1899, p. 325.
[6] Zeitschrift fur Heilkunde, 1902, Band xxiii., p. 366.

These brothers presented a singularity in gait, walking with a slight bend or incline at the hips. At first I thought the elder brother had had spinal disease but the spine was straight and the motion of the hip joints was perfect. He had had rheumatic pains in many joints and there were several Heberden's nodes.

Dr. Ogden of Milwaukee writes with reference to his alkaptonuria patient, whose condition was described in the *Zeitschrift für Physiologische Chemie*, 1895, that "the colour of the inside of each concha is a pearly, light greyish lead-blue, much the colour of the inside of some of our common mussel shells." This is evidently staining of the cartilages similar to that which exists in the two patients here described and in Albrecht's case.

There is no question that these are cases of ochronosis in long standing [illegible] port Albrecht's [illegible] laginous tissues [illegible] of metabolism which we have heretofore only recognised by the changes in the urine. The condition is thus brought within the range of the clinical physician. *Fortunately it is not* of much moment, so far as we know, and in the recorded cases there have been no symptoms directly due to the alkaptonuria. Dr. Garrod informs me that there are only two recorded post-mortem examinations in alkaptonuria cases. In Fürbringer's case[7] the patient, a male, aged 29 years, died from phthisis. There is no mention of the duration of the alkaptonuria. The necropsy was made by Thoma and the description is complete. Blackening with alkalies was looked for in the body fluids, but there is no mention of blackening of the cartilages. In von Moraczewski's case (a woman, *aged 43 years) the alkaptonuria was supposed to be* of late development. There is no mention of the cartilages in the protocol of the post-mortem examination. Some of the cases of ochronosis have not been in alkaptonuria and, as Dr. Garrod writes, it looks as if possibly even the very few cases described may belong to two distinct classes. Of the three cases in which black urine is mentioned two at any rate seem not to have been in alkaptonuria, and in Albrecht's patient Zdarek could not find in the fresh urine either homogentisic or uroleucic acid.

Baltimore, U.S.A.

SOME SIMPLE EXPEDIENTS IN PHYSICAL THERAPEUTICS.[1]

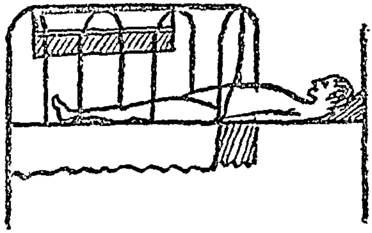
BY W. ESSEX WYNTER, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,

PHYSICIAN TO MIDDLESEX HOSPITAL.

IN the whole range of therapeutics there is no more important subject than the proper and efficient treatment of pyrexia. Without, however, entering upon an exhaustive consideration of so important a theme it will be allowed that while minor and transient degrees of fever can safely be left alone or dealt with by the various antipyretic drugs, and the more serious forms of hyperpyrexia demand rigorous application of cold in the form of bath or ice pack, there remains an intermediate class of continuous fever in which the repeated use of either of these modes of treatment is undesirable. It is only necessary [illegible] ment to say that all [illegible] depressant action on [illegible] tion is apt to induce [illegible] cases in which steady heart action affords the main road to recovery. On the other hand, while the application of cold to the surface, acting as it does as a tonic to the circulation, effects the reduction of temperature without involving this risk, many of the methods employed for the purpose, such as sponging, packing, and bathing, though undeniably efficacious and wholesome, possess undoubted drawbacks in practice. The use of water in any way involves trouble and difficulty on the part of attendants, not always skilful when available, and such proceedings, adapted as they must be to the severity of the case and the endurance of the patient, and liable if mismanaged to serious mishap, necessarily involve the presence of the medical attendant for a longer period and on more frequent occasions than may be convenient or even possible.

Taking these considerations into account, especially in such a state of continued pyrexia as that of typhoid fever, the system known as *cradling* offers undeniable advantages. It consists merely in arranging a sort of tent over the bed in which the patient lies naked or very lightly covered. The two ends may be left partly open to encourage a current of air or the effect may be intensified by suspending a trough inside containing broken ice. In hospital the tent is usually made of metal hoops covered by a sheet or blanket but in an ordinary bedstead a rod or cord extending horizontally about two feet above the patient and attached to the head- and foot-pieces is all that is necessary. In this way the surface of the body can be exposed indefinitely to an atmospheric temperature of about 60° F. which can be easily regulated, the natural cooling effect of radiation and evaporation being thus enhanced. The great advantages of this method are its simplicity; its remarkable efficiency, the continuity of effect being not only of value in continued febrile states but in reducing high temperatures; its comfort to the patient; the avoidance of the repeated shock and disturbance of applying water; and the freedom and security it gives to the medical attendant who is not called upon to cope with periodical alarming temperatures but can leave the nurse to meet the variations of the thermometer within a reduced range by regulating the draught or by applying ice or a blanket within the tent as indications require (see Fig. 1).

FIG. 1.



Cradle with ice trough.

In dealing with children whose consent and collaboration in times of sickness are less easily obtained than those of adults, as also in delirium and in highly nervous subjects, cradling is of special service and may be continued for ten or 14 days if necessary.

While considering the means of reducing temperature generally it may be useful to mention a simple method for keeping the head cool and controlling the circulation in cases of injuries and diseases of that part. In meningitis, skull fractures, and concussion, and sometimes in the delirium of fever, it has been the practice to apply cold to the head by means of an ice cap or simple bag, or perhaps only by evaporating lotion to the forehead. It is scarcely necessary to remind anyone that, with perhaps the exception of the last named, there is little satisfaction to the patient in any of these, and in unconsciousness or delirium it may exceed the powers of the nurse to maintain any contact at all. Moreover, the regions of the head to which these means are applied—the forehead and *vertex—are already the cooler on account of their position, being in the periphery of the* circulation and in addition freely exposed to the effect of radiation and evaporation. The part to which cold can be more profitably applied is the occiput and the nape of the neck and this can be done without difficulty or discomfort by using as a pillow an ordinary rubber water-bottle filled with ice-cold water and crushed ice and having a smooth towel pinned round it as a pillow-case. The substitution of this for the troublesome and inefficient appliances hitherto recommended in head cases has justly earned the gratitude both of patients and nurses and is particularly satisfactory to the medical attendant, as when ordering his patient "cold to the head" he can see that he gets it. In the delirium of fever, besides the local effect, this method has the great [illegible] so reliev- [illegible] For the [illegible] tic water [illegible] pillow is an absolute luxury, and while he is lying flat as in typhoid fever it is more convenient than an ordinary bolster. If filled with water containing shaved or finely crushed ice the bottle does not require refilling more than once in from four to six hours. The tension can be regulated to a nicety by the quantity used and it is as well to exclude air, both to insure the better conduction of heat and to avoid gurgling noises on movement of the head.

---

[7] [illegible]

[1] [illegible]

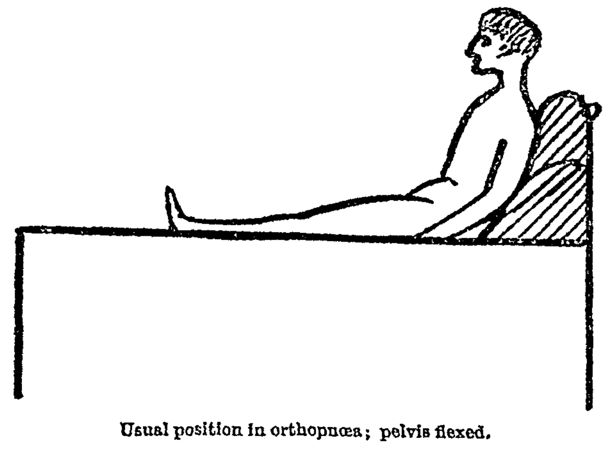
Before bidding good-bye to the rubber water-bottle it may be worth while recalling what many patients have discovered for themselves, that when hot it supplies a convenient and efficient substitute for a poultice or fomentation, more particularly in cases of colic or local pain, though, of course, the heat is dry instead of moist. Owing to its collapsable nature the rubber bottle, suspended, inverted, and fitted with a suitable arrangement of tubing, has been employed as a reservoir in administering douches of various kinds; this might possibly be useful in an emergency.

Having devoted the foregoing to a consideration of the application of cold in the treatment of certain morbid conditions, it seems appropriate to mention here some ready methods of applying heat and the diseases in which it is useful. Radiant heat from a red-hot coal fire, *pace* asseverations to the contrary, is effective in subduing the almost unbearable irritation of chilblains. This irritation is at its worst during about two hours in the 24, and can be controlled for that occasion by holding the affected part for a minute or two as near the fire as can be tolerated with considerable fortitude; steeping in very hot water approximates to this. The trouble recurs the next day but it can be abolished in the same way, and after three or four repetitions a cure is effected. Relief of the itching in psoriasis and eczema has also been found by many patients to follow exposure of the part to strong heat of a fire, a lamp, or water, and it is recorded of the Emperor Napoleon I. that he spent much time sitting in hot baths for the relief of a life-long eczema of the thighs which caused him serious torment. There is probably nothing which produces such unbearable irritation as pruritus ani, rendered more difficult to relieve by the comparative inaccessibility of the part. This, however, may be mitigated by the use of hot douches, the temperature being borne by some as high as 130°. Where this cannot be arranged the application of a hot cone such as an inverted soda-water bottle filled with hot water will serve instead. Though in all these cases relief is only temporary it is greatly valued by the patient, and the rest from friction locally and respite to the nervous system ultimately lead to cure.

Another simple and effective means of applying dry heat particularly to joints and surfaces is afforded by silver sand loosely inclosed in a linen-lined flannel bag, baked in an oven, and closely packed round the part. The heat lasts for half an hour and is both comforting and curative in chronic joint affections and lumbago or muscular rheumatism. On a more extensive scale the subjects of rheumatoid arthritis in Egypt spend hours buried in the hot sand with remarkable benefit.

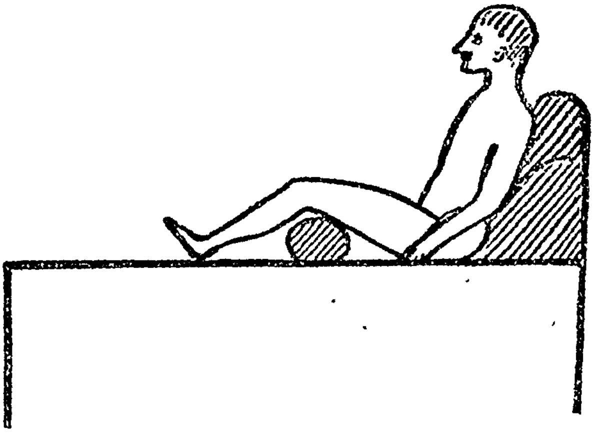
Patients with pulmonary or cardiac disease who are compelled by orthopnœa to sit up in bed suffer much in addition to their other troubles from the discomfort and insecurity of their position. On an ordinary flat mattress, and perhaps more so on a feather one, the pelvis is flexed and the weight is received obliquely on the lower part of the sacrum and coccyx which, owing to its irregularity and the thinness of its covering, soon becomes sore (Fig. 2). Moreover, the body, supported only by what engineers term "skin friction," tends to slide away from support, the clothes become "rucked," and the patient is only maintained in his precarious position by muscular effort and the frequent attentions of the nurse. By placing a firm bolster across the middle of the bed below the mattress a double-inclined plane can be formed like a Singapore chair which with the pillows or bed-rest affords thoroughly comfortable and firm support (Fig. 3). The weight of the body is then received through the ischial tuberosities in a line with the spine without tendency to displacement and its attendant troubles or any necessity for muscular effort. The abolition, too, of the flexure of the lumbar spine does away with the consequent compression of the abdomen and the sense of suffocation and oppressive flatulence which so often afflict patients in this position. The bolster may be put in position while making the bed, otherwise it is best arranged by lifting the lower half of the mattress and pushing it up from below till it meets and supports the buttocks. Those who have not attempted to sit up in bed for hours or perhaps days and nights at a stretch can scarcely realise the effort and discomfort it involves and the amount of ease this form of support affords. Not the least of its benefits is the partial flexion of the knees with support, relieving the tension on the nerves and tendons at the back of the thigh as well as the pressure on the heels, while the security from slipping downwards permits the weight of the trunk to be freely transferred to the pillows at the back.

Fig. 2.



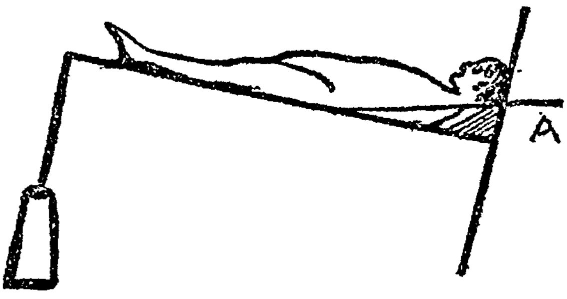
Usual position in orthopnœa; pelvis flexed.

Fig. 3.



Position with bolster under the mattress.

Fig. 4.



Feet raised in pleural effusion. A, Level of fluid.

A very simple method of affording support to a patient sitting up for brief periods after an enfeebling illness is to pass an ordinary roller towel round the back below the armpits and to make it fast to the foot of the bed. This of course does not prevent him slipping down and involves more confinement of the chest than one suffering from respiratory difficulty would tolerate, but as a simple mechanical support in uncomplicated convalescence it is often useful.

While considering the decubitus in pulmonary disease I would allude to the benefit in certain cases of pleurisy with effusion of raising the foot of the bed about 12 inches, so as to make the shoulders the lowest point, the patient lying supine or on the affected side (Fig. 4) The position is perfectly comfortable and quite easy to maintain continuously, the head being raised on an ordinary pillow not too high. The cases in question are those of pleurisy with effusion in which the fluid continues to rise to the top of the chest, recurring after tapping, and which are usually unaccompanied by pain though there is *some fever. In these instances experience shows that the* pleurisy is at the upper part of the chest and is probably always associated with a tuberculous lesion in the upper lobe. These at least are the cases of which I am now speaking. In ordinary circumstances the fluid poured out naturally gravitates to the lowest part of the pleura; towards the diaphragm if the patient is up, or distributes itself over the back if he lies in bed In either case it flows away from the seat of inflammation in the upper lobe and incapacitates the lower and presumably healthy portion of the lung, by its bulk also displacing the heart and mediastinum and so limiting the expansion in some degree on the sound side Certainly, these patients apply for aid on account of dyspnœa rather than for any other symptoms. By the time the fluid has mounted to the dome of the pleura where it might do some good by bathing and separating the inflamed surfaces and collapsing and resting the diseased area of lung. it is usually considered necessary, on account of the dyspnœa combined with the physical signs of a full pleura, to perform paracentesis, and the chance of natural relief for the local inflammation is lost With a full pleura and dyspnœa there would be scarcely two opinions as to the necessity for tapping the chest, but after relief has been so obtained, or in cases where the condition has been recognised in an earlier stage, decided benefit results from this position. The temperature falls and the exudation ceases, so that subsequent tappings are not required and recovery is more rapid. The ultimate effect on the pulmonary lesion is probably favourable; the treatment is, at all events, in accord with the generally received opinion of physicians that functional inactivity and collapse due to the presence of effusion round a tuberculous lung tend to arrest the progress of phthisis and should not be unnecessarily interfered with Whether there is a lessened tendency to the formation of adhesions it is difficult to say, but undoubtedly adhesions are infinitely more common in the upper half of the pleura, usually the dry areas, than in the lower half, the usual site of accumulation of fluid. Of course there are many instances of pleurisy accompanied by *pain and friction at the base followed by* effusion, both tuberculous and otherwise, but of these I am not now speaking.

The greater freedom of movement in the lower as compared with the upper half of the chest probably accounts for the greater frequency and severity of pain where the lower part is affected by pleurisy. On lying down, however, expansion of the upper lobes increases at the expense of the lower and this change is probably answerable for both the occurrence of pleuritic pain and the constant exacerbation of cough so notable in the subjects of pulmonary tuberculosis on assuming the recumbent position. In addition to posture the movements of the arms have a decided influence on expansion and contraction of the chest and after the febrile period rhythmic exercise, as in tolling a bell, definitely accelerates absorption of fluid from the pleural cavity. The influence of violent exertion in inducing dryness of serous cavities is familiarly illustrated by a "stitch in the side."

Enteroptosis.—A condition taken into account in recent years, though formerly overlooked or regarded as hardly beyond the bounds of the normal, is that laxity of attachment of the abdominal viscera which leads to their displacement on assuming the erect position, this being attended by a sensation of dragging and various functional disturbances. When this affects the kidneys only, and particularly when unilateral, a remedy is found in artificial fixation by operation. There are, however, many instances of the kind in which this is not resorted to and where the looseness extends to many or all the viscera operation is practically out of the question. If these patients, who, so far as I know, are all women, are to have any ease apart from the recumbent posture some form of mechanical support to the abdomen is necessary. Various forms of belts and pads are employed, but comparatively recently a sufficient number of cases of this sort have been submitted to one particular form of treatment to prove its general value and applicability. This consists in applying a nearly rigid support to the anterior wall of the abdomen by means of plates of sheet lead, trusting to the elasticity of the contained gases to furnish a resilient padding to the solid organs and to distribute the pressure exerted. To prepare these plates a pattern is first cut in paper by shaping a piece to cover the entire front from loin to loin and ensiform to pubes, taking care to leave a *space of half an inch at the bony points and margins.* By folding along the middle and trimming symmetry is assured and by cutting off the folded part an inch wide sufficient space is allowed for the edges to come together without overlapping. These patterns are then cut out of five-pound sheet lead and sewn into brown holland cases, which are stitched to the inner aspect of the corsets after temporarily adjusting with pins in the proper position. The corsets should be long as the two plates are liable to bend and to crack if they extend below them. The apparatus should be applied carefully before the patient arises from the recumbent posture so as to apply the pressure while the organs retain their normal position; the patient can then rise and get about without displacement occurring By this means it is certainly possible for a woman to get up at once and to go about her ordinary avocations in comparative comfort, free from the disability, pain, and vomiting which without such aid force her to maintain a recumbent position. The steady retention of the viscera in their proper place and the improved nutrition and health that ensue usually enable the patient to dispense with these artificial supports after three or four months, though in the mean time they may require renewing. It is useful therefore to retain the original paper pattern or a copy. As the plates are worn they adapt themselves to the figure, becoming more comfortable and effective, and should not therefore be straightened out when removed at night. Considering the difficulty of making any suggestion for the relief of enteroptosis and the great disability it involves this simple and harmless method will prove a welcome aid.

Reflex inhibition.—Many people are aware that pressure about the bridge of the nose or between the eyebrows will arrest an inconvenient sneeze, but it is not so generally known that gentle massage of the cricoid cartilage will usually arrest hiccough, especially in infants and young children in whom it most frequently occurs. So simple a proceeding could scarcely be expected to stop this distressing symptom in its severe form dependent on serious organic disease of the abdomen, but as a means of relieving the temporary attacks due to gastric disturbance, such as those ensuing on the ingestion of hot condiments, it is very efficacious. I have myself frequently found it of practical service while attending children. Stimulation of Arnold's nerve in the external auditory meatus or behind the ear is also effective.

Some forms of vomiting can be checked by counter irritation of the epigastrium by means of a blister or a mustard leaf or plaster. It may be worth mentioning that the least disagreeable mode of obtaining a rubefacient effect with mustard is to rub the dry flour into cotton wool and to apply this to the skin closely covered with oilsilk, when the natural moisture of the skin gradually brings the sulphocyanate of allyl into action, producing a mild calefacient effect which can be tolerated for several hours if necessary with [illegible] peripheral [illegible] the heart [illegible] articularly when the temperature is above normal, and I can recall several instances of typhoid fever in which this means of simultaneously checking vomiting and reducing temperature has proved of immediate service. Considering how inappropriate many remedies for vomiting are, which involve ingestion and digestion by an organ which can neither retain nor absorb, any indirect method such as this will often afford useful help where the long list of anti emetics are disqualified at once simply because they are internal remedies. Until quite recently we scarcely possessed an alternative to these, saving the subcutaneous injection of morphine, the remote effects of which often forbade its employment; no apology therefore is needed for mentioning another and quite new one though not actually germane to my present text. This is the continuous or repeated inhalation of oxygen. As to the rationale of the treatment I am not aware that physiologists have expressed an opinion, unless it is to suggest a parallel to the state of apnœa. I can, however, testify from its frequent employment in various forms of persistent vomiting—functional, reflex, and organic—that, so far, no means has proved so uniformly effectual. The inhalation of oxygen, and there is little trouble now in obtaining a cylinder, has this great advantage: it is perfectly harmless under all conditions and its administration may be repeated as often and continued as long as may be necessary and by comparatively inexperienced hands. It requires no effort on the part of the patient beyond that of ordinary respiration and involves no suffering or after-effects of a disagreeable character. Being administered by the lungs it not only acts independently of vomiting, which may continue for a time, but is peculiarly serviceable in such cases as those of gastric neurosis, irritability, inflammation or ulcer, in which it is undesirable or useless to introduce anything into the stomach, or after laparotomy where, in addition to this, retching is particularly obnoxious on account of the strain on the abdominal wound. Perhaps the most notable instance of its utility that could be offered was that of a nurse recently under my care for perforated gastric ulcer, involving laparotomy and suture of the stomach, where nothing could be given by the mouth and where the oxygen speedily arrested the vomiting following the anæsthetic and a recurrence some days later.

Other examples of reflex action, such as the contraction of the uterus following manipulation of the breast or distension of the vagina. sometimes contributory in accelerating labour or arresting post-partum hæmorrhage, are too familiar to need mentioning; as is the effect of dilatation of the anus or distension of the rectum in exciting contraction and evacuation of the colon. There is, however, a well-established reflex inhibition of the detrusor urinæ, illustrated in physiology by the arrest of micturition on stimulation of the sciatic nerve and in clinical experience by retention of urine, usually inseparable from operations about the anus and perineum. Apart however, from direct interference with the sciatic nerve, the effect of stimulation of its branches by pressing or pinching the skin below the buttock, in diminishing the desire for micturition, is readily demonstrated and may well be turned to account in dealing with cases of irritability of the bladder of nervous origin, and those more numerous and troublesome instances of enuresis in children for which there are so many remedies and so few cures, where a blister or even a calefacient plaster, made by moistening ordinary strapping with tincture of cantharides, would probably exercise sufficient restraint.

Internal hæmorrhage.—It is fortunately a very rare event for sudden internal hæmorrhage to prove immediately fatal unless due to the rupture of an aortic aneurysm, but it sometimes happens that before it is arrested by the occurrence of fainting and lowered blood pressure either so much blood has been lost as to involve tardy convalescence or the hæmorrhage, of little consequence in itself, causes serious damage to the organ in which it escapes, as occurs in the brain and lungs. It has been urged in such cases that it were better to induce syncope and cessation of hæmorrhage, either continuous or recurrent, by phlebotomy than to permit the continuance of the internal hæmorrhage at the risk of important tissues. But where such loss is already threatening life one naturally hesitates to induce further loss by other means, and the administration of antimony and other depressants has been suggested and carried out with a view to "bleed the patient into his own veins." This procedure, though useful in some instances of recurrent hæmoptysis and others of a slow and continuous nature, is hardly suited to emergencies, but a somewhat similar effect without the prostration and more under control can be obtained by applying elastic bands to the proximal end of the limbs. A moderate constriction is sufficient to retain the blood in the veins without arresting the flow in the arteries, so as to trap the fluid and to prevent its return to the heart. In this way a degree of anæmia in the central part of the circulation is obtained without further bloodshed, favourable to cessation of hæmorrhage and coagulation at the bleeding point, while the surplus remains in the limbs against future needs.

Whilst dealing with hæmorrhage it may be useful to allude to that common form epistaxis, which used to be treated by the barbarous practice of plugging the anterior and posterior nares. Now, happily, we have a remedy in a spray of adrenalin solution, 1 in 1000, which rarely fails in immediately arresting the bleeding and nothing could be cleaner, more inoffensive, or easier of application. But in the very exceptional instances in which it may be necessary to apply pressure this can now be done by means of a suitable rubber bladder introduced and inflated through the nostril and known as a "condom." Before this instrument was invented, and even now in its absence, an effectual plug for the nose could be improvised out of a piece of raw bacon fat from two to three inches long and of sufficient bulk, cut into appropriate shape, so that it can be just squeezed into the nostril, where it should remain several hours. It forms an efficient plug, is always at hand, and is not uncomfortable, neither is it so difficult to apply nor liable to adhere in its place or to lead to soreness and septic changes as are tampons. In minor cases the popular ideas of applying cold to the nape of the neck or raising the arms above the head are physiologically correct, as both tend to diminish the calibre of the vessels and to reduce the local tension and blood flow, but the plan of lying flat on the back, though tending to lower the force and frequency of the heart beat, is chiefly operative in causing the escaping blood to disappear into the pharynx. Perhaps as simple and effective a method of arresting minor forms of epistaxis as any is merely "champing" the jaws, when the blood flow of the internal maxillary artery is diverted to the muscles of mastication and the smaller terminal vessels in the nose are starved and cease to bleed.

Wimpole-street, W.

SPIRAL FORMATIONS IN RELATION TO WALKING, SWIMMING, AND FLYING.

BY J. BELL PETTIGREW, M.D., F.R.C.P. EDIN., LL.D., F.R.S., &c.,
CHANDOS PROFESSOR OF MEDICINE AND ANATOMY AT THE UNIVERSITY OF ST. ANDREWS.

THE universality of the spiral in nature is a subject alike for surprise and reflection. As regards beauty of outline, the spiral transcends all other forms and is a source of pleasure. The spiral occurs very frequently both in the inorganic and organic kingdoms and, as I hope to show in the present article, has its own special uses. It is seen on a grand scale in the spiral arrangements of nebulæ, in the whirlwind and whirlpool, in the waterspout and the sand-storm, in the cyclone, and other natural phenomena. As concerns living things it is fundamental and manifests itself in the most rudimentary plants and animals, in the cells and seeds of the higher plants, and in the spermatozoids of the more complex animals. It makes its appearance, so to speak, at the very threshold of life and can be traced through the whole vegetable and animal kingdoms up to man himself. It is seen in spiral stems, spiral tendrils, spiral leaves, spiral flowers, spiral fruits, &c., in plants, and in spiral bones and joints, spiral muscles, spiral horns, spiral teeth, spiral shells, &c., in animals. It not only abounds in every department of plant life but it also lends itself freely to the construction of large numbers of external and internal skeletons in animals. All the hard and soft parts of the higher animals are, with few exceptions, dominated by it. It is a thing not of accident but of design.

Apart from the beauty and grace which inhere in every variety of spiral I think I can trace in it a hidden and far-reaching purpose. Indeed, I can show that not only do spirals enter largely into the formation of plants and animals but also that the complicated movements of climbing plants and tendrils and of walking, swimming, and flying are directly traceable to their existence; nay, more, that the circulation of the blood in birds and mammals is in great measure due to the ventricles of the heart being composed of powerful combinations of spiral muscular fibres. As a matter of fact, the blood in birds and mammals is forced by the ventricles into the larger blood-vessels (especially the aorta) by spiral movements which cause it to gyrate within them much in the same way that a rifle bullet is made to gyrate within a rifle when the weapon is discharged. The ancient and grim phrase "wringing the heart's blood" has, curiously enough, its foundation in fact. The spiral ventricles of the heart in birds and mammals are typical of many other structures. In the human species the stomach, bladder, uterus, &c., are all composed of spiral, figure-of 8 muscular fibres and, strange as it may appear, the food, the urine, and even the fœtus, are subjected to spiral pressure when being passed on and extruded. In parturition in the human female the offspring make a distinctly spiral exit, a result produced partly by the movements of the uterus and partly by the configuration of the pelvis. The heart is at once the most spiral and powerful muscle in the body, if the amount of work performed by it and its unceasing activity be taken into account. The ventricles of the heart are also by far the most complicated muscles known. Their arrangement forms a veritable Gordian knot in anatomy, the famous anatomists, Vesalius, Albinus, Haller, and De Blainville all confessing their inability to unravel it. The ventricles of the heart are deserving of very particular attention, both as regards their structure and function, from the fact that they throw a flood of light on muscular arrangements and movements as a whole.

All muscles, voluntary and involuntary, are fundamentally spiral in their nature. Sometimes only a curve or portion of a spiral can be distinguished, at other times entire systems of double reversing spirals can be made out. The involuntary muscular fibres of the ventricles of the heart in the bird and mammal afford beautiful examples of complicated double spirals, and one has only to study the spiral configuration of the bones (especially the long bones) as seen in the extremities of birds and mammals and the spiral configuration of the joints connected therewith to be convinced that the voluntary muscles must not only be spirally arranged but that they must also act spirally. The spiral action of the voluntary muscles is most observable where they act upon spiral joints, but it is also well seen where they act upon *universal or ball-and-socket joints, such as the shoulder-* and hip joints. It is in virtue of the spiral action of the muscular masses connected with ball-and-socket and with spiral hinge and other joints that circumduction and partial rotation of the arms and legs are possible. It is a curious fact that the muscular masses which invest and actuate ball-and-socket joints have their fibres arranged very much as the muscular fibres of the ventricles of the heart in birds and mammals are arranged—that is, they run in vertical, oblique, and transverse spiral directions. The muscles of the pharynx, œsophagus, and tongue follow the same general plan. The voluntary and involuntary muscles, it will be seen, are arranged in spiral cycles, the only difference between the two kinds of muscles being that in certain of the hollow viscera, say the ventricles of the heart of the bird and mammal, the involuntary muscles are arranged round *spiral cavities*, whereas the voluntary muscles, say those occurring in the extremities of the bird and mammal, are arranged round *spiral bones and spiral and other joints.* The involuntary hollow muscles communicate, as stated, a spiral impulse to the substances contained within them; the voluntary solid muscles, on the other hand, cause the extremities and other parts of the body to make spiral movements and describe spiral trajectories.

Muscles, whether voluntary or involuntary, in every instance act harmoniously and to given ends. Their movements are never perfunctory or haphazard. There is no such thing as flexor muscles forcibly and violently dragging out extensors, pronators supinators, abductors adductors, and the converse. This would be a mere waste of power, as it would necessitate one muscle contending with another, while each muscle has the same object in view—namely, the moving of certain bones or parts. When the flexor muscles [illegible]

[illegible] in groups but they require to be trained to prevent antagonistic action. Walking, swimming, and flying have all to be learned and the training consists in teaching the several muscles and groups of muscles to act in concert at stated intervals. Antagonism in muscular action would be fatal to the performance of muscular work. As a matter of fact, all muscles are invested with a double vital power whereby they can shorten and elongate, or what is the same thing close and open, by alternate centripetal and centrifugal movements, the flexor muscles closing and shortening when the extensor muscles open and elongate, and *vice versâ.*

In no part of the body do curves and spirals play a more prominent part than in the spinal column, the pelvis, shoulders, and extremities. In man the spinal column consists of four exquisite curves, the convexities of the cervical and abdominal curves being directed forward and the convexities of the thoracic and pelvic curves being directed backward. This double system of curves diffuses shocks equally from above and below and presents a line of beauty not matched even by that of the famous limner, Hogarth. The pelvis consists of a series of most beautiful arches (some of them skew), and the bones composing the arches are twisted in various directions. Similar remarks apply to the scapulæ, the clavicles, and the ribs. The bones of the extremities, as already pointed out, are spiral in their nature, but they are also in the majority of cases slightly bent in the direction of their length, a circumstance which contributes greatly alike to their elasticity and to their strength. Additional strength and elasticity are obtained, in the case of the arm and thigh bones (humerus and femur), by the bones being provided with short, oblique necks where they articulate with the body, an arrangement calculated to neutralise impacts of all kinds from the hands, feet, and other parts of the extremities.

In virtue of the spiral arrangements which obtain in the muscles and in the bones and joints of the extremities the limbs of bipeds and quadrupeds in walking and running describe alternating, complemental, figure-of 8 curves arranged in different planes and which approximate but never interlock. A locking movement of the extremities would render locomotion impossible. It follows that men and animals can, by the aid of their extremities which move in free spiral curves, perform long journeys without difficulty. As is well known, the bodies of vertebrate animals are bilaterally symmetrical. This is especially true of man who may be regarded as the paragon of living forms. In order to bring about this bilateral symmetry the body is composed of right- and left-handed spiral segments, the one slightly *overlapping and dominating the other. This view is favoured* by the fact that antelopes and other animals which grow spiral horns invariably produce a right-handed spiral on one side of the head and a left-handed spiral on the other or opposite side of the head. The overlapping, stronger, and more active segment or half of the body practically settles the question of right- and left handedness, the individual being right handed when the right segment and left-handed when the left segment is in the ascendancy. The brain, as the controlling agent, is a leading factor in determining whether an individual is to be right- or left handed.

Without entering into the subject too minutely it is safe to assert that the one side of the body is almost invariably stronger than the other, and that this greater strength, however produced, inclines the individual to use that side and the extremities of that side the most This is well seen in the lead taken by one or other extremity in walking. If the eyes be blindfolded it is not possible to walk in a perfectly straight line. It is found, moreover, next to impossible to walk in a perfectly straight line even when the eyes are open and fixed on a given object. *Unconsciously*, the heavier, stronger, and more active half of the body asserts itself and the individual swerves in curves to the right or left in spite of himself. The curved spiral movements of the limbs and the trend to the right or left in particular instances explain why natural footpaths in fields and waste places are almost invariably tortuous and winding. The spiral arrangements to which reference has been made culminate in the movements of walking, swimming, and flying. These important movements, on which the lives of the higher animals largely depend, are, as I showed in 1867 and subsequently,[1] distinctly spiral in their nature. When a man walks he twists his body at the shoulders and hips diagonally, the right arm and left leg advancing together to form one step, the left arm and right leg advancing together to form a second step. The right arm and left leg in walking make opposite spiral curves and these are crossed by similar curves made by the left arm and right leg, the result being a series of double, figure-of-8 curves. The same thing happens when a bird swims by the aid of its feet. In this case the right leg with the right webbed foot fully expanded is during the effective stroke thrust in a backward direction and makes a right-handed curve; the right foot, which during the non-effective stroke is closed and drawn towards the body, making a left handed curve. The left leg and foot perform similar movements and as the right and left legs and feet act alternately, double or figure-of-8 curves are generated. Similar remarks are to be made of the movements of quadrupeds. These, however, are slightly more complicated. Thus, in the walk of the horse the body is alternately supported on diagonals formed by the right fore and left hind legs and the converse; on laterals formed by the right fore and right hind legs and the converse; and on tripods formed by the two fore legs and one hind leg and the converse. In one stride the body is successively supported (1) by the two hind legs and the left fore leg; (2) by the left fore and right hind legs; (3) by the two fore and right hind legs; (4) by the right fore and right hind legs; (5) by the right fore and the two hind legs; (6) by the right fore and left hind legs; (7) by the two fore and left hind legs; and (8) by the left fore and left hind legs.

[1] On the Various Modes of Flight in Relation to Aeronautics (Proceedings of the Royal Institution of Great Britain, 1867); on the Mechanical Appliances by which Flight is attained in the Animal [illegible] Society, vol xxvi. 1867); on [illegible] the Royal Society of Edin- [illegible] ocomotion (Anglo American

The supports formed by the legs of the horse vary in the several paces, such as the trot, the gallop, the amble, &c. The outstanding feature in all the paces is the twisting movements of the body at the shoulders and hips, and the sinuous, double, figure-of-8 curves made by the legs and feet on leaving and reaching the ground. These double-curved movements are well seen in the swimming of the fish, especially the long-bodied fishes. In swimming the body of the fish is thrown into alternating, complemental, cephalic, and caudal curves. Generally the sinuous double-curve movements can be traced also in the pectoral fins of fishes, these fins being the homologues of the anterior extremities of quadrupeds and bipeds. They invariably occur in the tail, which is lashed from side to side by a sculling movement. The tail of the fish is made to vibrate laterally, and while so engaged it twists upon its root or axis in such a manner as to produce double curve, figure-of 8 movements. The pectoral and caudal fins of fishes are of a generally triangular shape and are beautifully graduated, tapering, elastic structures. They closely resemble wings both in structure and function. They are all propelling organs. If the pectoral fin of the thresher shark (*Carcharias vulpes*) be examined it will be found that it is triangular-shaped, thick, and semi-rigid at the root and along the anterior margin and thin and elastic at the tip and along the posterior margin. This is the type of all wings, as an inspection of the wing of an insect, bird, or bat will show. Wings are slightly twisted upon themselves structurally and are screws functionally. The main difference between the pectoral fins of the shark and the wings of flying creatures consists in the greatly increased size of the latter. In only one case—*namely, that of the flying fish*—do the pectoral fins approach the wings in dimension. The flippers of the dolphin, whale, and sea-bear resemble the pectoral fins of the shark both in *form and function. The fins and tails* of fishes and the flippers of sea mammals simply propel. The wings of insects, birds, and bats propel, elevate, and sustain. Fins, wings, and flippers, however, act on a common principle, which finds its expression in the sinuous, double curve, figure-of-8 movements referred to in the walking of the quadruped and biped and in the swimming of the bird and fish. That wings act as explained can readily be verified by holding a bluebottle fly or a bee against a dark background in a strong light when the wings are vibrating rapidly. The blur or impression produced on the eye of the spectator by the swiftly-moving wing is twisted figure-of 8 fashion, a circumstance due to a change of plane in the wing and to *the fact that the* wing acts spirally in two directions as it hastens to and fro, the double curves forming one-half of the 8 being developed during the forward stroke and the *double curves forming* the other half of the 8 being developed during the back or return stroke. In free flight the figure-of-8 is opened out spirally, the wing in this case making a *waved-trajectory in* space. In the insect the wing acts more horizontally than in the bird and bat. In the bird and bat the spiral figure-of 8 movements made by the wings can *be readily detected* by a practised eye and careful observation. When the wings of the bird and bat are made to vibrate in captive or slow flight the tips of the wings make *more or less* vertical figure-of-8 trajectories In free rapid flight the figures-of-8 made by the wings are opened out and spirally unravelled and form waved trajectories—as in insects. To this there is no exception, as I have very fully convinced myself alike by observation and experiment. In birds and bats the wings are more or less folded and shortened during the up-strokes and expanded and lengthened during the down-strokes. The wings of birds and bats, as I first pointed out in 1867, strike downwards and *forwards* during the down stroke and upwards and *forwards* during the up-stroke. *This view, wholly opposed to prevailing beliefs,* was much debated at the time, but has been strikingly and amply corroborated by instantaneous photographs of flying birds taken by Mr. E. Muybridge and others. In these photographs—those of the pigeon, e.g.—the tips of the wings at the *beginning* of the down-stroke are as far back as the extremity of the tail, whereas at the *end* of the down-stroke they are in advance of the beak of the bird the whole length of the body or more. The old idea was that the wings *pushed* the body of the flying creature forward; in reality, the wings always fly in advance of the body and *pull* it forward. The result is the same, but the *modus operandi* is wholly different.

In all natural wings and in all artificial wings properly constructed the figure-of-8 and waved movements are invariably developed in captive and free flight. The great interest taken in artificial flight of late years invests the subject of the present article with a new zest and this has been heightened by the recent publication (1903) of a small work by Mr. Theodore Andrea Cook, M.A., entitled "Spirals in Nature and Art: a Study of Spiral Formations based on the Manuscripts of Leonardo da Vinci, with special reference to the Architecture of the Open Staircase at Blois, in Touraine." Mr. Cook in the work in question has attributed, rightly or wrongly, to that celebrated artist, architect, and engineer a large number of the most important discoveries of modern times. I say rightly or wrongly as Mr. Cook adduces no proof to show that Leonardo actually made the discoveries which he has assigned to him, proofs, it appears to me, being required in the case of a savant who died several centuries ago and whose writings are very little known. In the matter of flight the claims which Mr. Cook makes for Leonardo are wholly unwarranted—indeed, wholly opposed to facts. Thus at pages 153 and 154 of his book he says: "The downward stroke of a bird's wing which is *supposed to be so new a revelation* of the instantaneous camera was noted independently by Leonardo. He observed, too, that as the tips of a bird's wings in flight go up and down as well as onwards they make a spiral in the air which is adapted to the strength of wind resistance it has to encounter, and he made use of this observation in his theory of flying machines. His brain was able to infer what no human eye could really see, and when he noted that the spiral *formation of a screw was suggested by the movement of* a flying bird it was not till 400 years afterwards that the truth of the inference could be visibly demonstrated." Mr. Cook, in support of the claim which he sets up for Leonardo, appropriates (vide Fig 45 of his book) two of my original figures which he assigns to Leonardo without acknowledgment. In this connexion I have to state that Mr. Cook in a recent issue of *Nature* (July 30th. 1903) has frankly admitted that he inadvertently appropriated my figures. In his apology, however, he avers that my figures are of very little importance to his argument. He gives with the one hand and takes with the other. The statement quoted above is altogether inaccurate and is not justified, even indirectly, by any passage or drawing occurring in the manuscripts of Leonardo da Vinci which I have carefully examined. As a matter of fact, Mr. Cook in his great admiration of Leonardo unwittingly reads into Leonardo's short treatise and notes on natural and artificial flight the discoveries on these subjects of the last 36 years. He gives to the sixteenth century what unquestionably belongs to the nineteenth century. Leonardo's chief work on flight, bearing the title "Codice sul Volo degli Uccelli e Varie Altre Materie," written in 1505, consists of a short manuscript of 27 small quarto pages, with simple sketch illustrations interspersed in the text. In addition he makes occasional references to flight in his other manuscripts, which are also illustrated. In none of Leonardo's manuscripts, however, and in none of his figures is the slightest hint given of his having any knowledge of the spiral movements made by the wing in flight or of the spiral structure of the wing itself. Mr. Cook, as explained, also claims that Leonardo knew the direction of the stroke of the wing as revealed by recent researches and proved by modern instantaneous photography. As a matter of fact, Leonardo gives a wholly inaccurate account of the direction of the stroke of the wing. He states that the wing *during the down-stroke* strikes downwards and *backwards*, whereas in reality, and as demonstrated by me in 1867, it strikes downwards and *forwards*.

In speaking of artificial flight Leonardo says: "The wings have to row downwards and backwards to support the machine on high, so that it moves forward." In speaking of natural flight he remarks: "If in its descent the bird rows backwards with its wings the bird will move rapidly; this happens because the wings strike the air which successively runs behind the bird to fill the void whence it comes." There is nothing in Leonardo's writings to show that he knew either the anatomy or physiology of the wing in the modern sense. *He certainly did not know* that the wing is a screw structurally and functionally; that in captive flight it makes a figure-of-8 track; that in free *flight the figure-of-8 is opened out to form first a spiral and* then a waved-trajectory, and that it strikes downwards and *forwards* during the down-stroke, the wings pulling and not *pushing* the bird as Leonardo and all those who followed him believed.

St. Andrews.

AN UNUSUAL FORM OF FAMILY PARALYSIS.

BY J. A. ORMEROD, M.A., M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL, ETC.

TWO brothers have recently been under my care in St. Bartholomew's Hospital who were affected as follows. The elder one had for many years suffered from weakness of the legs and within the last four months had developed weakness accompanied with muscular atrophy of one hand. The younger brother had been weak in the legs for ten months. A third brother, whom I saw once, appeared to have a similar though much slighter affection of the legs. The following notes are largely due to my house physician, Dr. A. H. Hogarth.

CASE 1.—A man, aged 23 years, tailor by trade, was admitted to Luke Ward on Oct. 28th, 1903, complaining *of difficulty in walking and of loss of power in the right* hand. Dragging of the legs in walking was first noticed 17 years ago—i.e., at the age of six years; for this he attended at the London Hospital. 14 *years ago he attended* at St. Bartholomew's Hospital and was given a pair of surgical boots. 11 years ago he attended for a short time at Guy's Hospital. At St. Thomas's Hospital, nine years ago, operations (probably of the nature of tenotomy) were performed on his feet. Six years ago he began to use a stick. Three years ago he noticed that the legs were wasting. Four months previously he had to give up work on account of weakness in the right hand and this weakness had been increasing since. Apart from these affections he had had *no illness of any* kind. He had been attending the orthopædic department under Mr. W. McAdam Eccles and the electrical department under Dr. H. Lewis Jones. He was a *well-nourished though rather* small-made man of typical Jewish aspect and appeared to be very intelligent. The internal viscera were normal. There was no disease of the spinal column. Speech was natural. The tongue was protruded straight; it was not wasted. He had no difficulty in swallowing. As regards the eyes nystagmus was present on fixing to either side, especially *to the left*, the movements being rather large, horizontal in direction, and not maintained for very long together. The pupils were normal; the fundus of the eyes was normal; there was no *affection of vision*.

The lower limbs were thinned, particularly in the lower part of the legs; but the wasting was uniform, not picking out any special muscles. (This refers to the general appearance; it should be added that Mr. McAdam Eccles, who kindly saw these patients for me, thought that there was loss of power and atrophy of the short muscles of the feet, particularly of the abductor hallucis and the flexor brevis digitorum.) There was extreme flatfoot on both sides. The bones of the ankles looked big and prominent *and there was some stiffness* at the ankles but apparently no actual disease of the joints themselves. Marked hallux varus was present on both sides. There was no definite loss of any movement, except it were for a slight weakness in plantar flexion of the foot; neither were the lower limbs rigid. As regards gait the patient required some support. He walked with his legs held rather stiffly and his knees a little bent. There was very little movement at the ankles; his toes seemed not to leave the ground. In addition his feet sometimes became crossed and he then staggered to one side and nearly fell down. The knee jerks were much increased on both sides. Ankle clonus was present on the right side always, sometimes on both. The plantar *reflexes* showed a well-marked extensor response on both sides. Electrical reactions (examined by Dr. Lewis Jones) were normal in the legs, the thighs, *and the glutei; they were not obtained in the interossei* pedis.

As regarded the upper limbs the muscles of the shoulders, *the upper arms*, and the *forearms* were natural. In the right hand there was marked wasting of the thenar and hypothenar eminences and of the interossei. Of the thumb movements adduction and opposition were lost and flexion was done by the long flexor. It was this loss of power in the thumb which was mainly complained of. The grip of this hand was weak. *In the left hand there was perhaps some wasting*, but not nearly so much as in the right, and the patient himself had no complaint to make of this hand. The tendon reactions were well marked in both upper limbs, the right more than the left. In response to *electrical stimulation* all muscles of the upper limbs acted normally excepting in the right hand, where there was total loss of reaction in all the thenar muscles *and in the first dorsal interosseous* muscle. The other dorsal interossei and the hypothenar muscles acted normally and there was no reaction of *degeneration. There was no sphincter* trouble and sensory functions were quite normal.

The patient had electrical baths daily. He stayed in the hospital a fortnight, during which time no change in his sym- [illegible] his feet less when [illegible] in the opinion that the peculiarity of gait could not be wholly ascribed to the condition of flatfoot. To summarise, this patient suffered from deformities of the feet and toes; from a paralytic affection of the lower limbs, partly of the spastic type (as shown by the increased tendon reactions and *the extensor* plantar reflexes), but accompanied by some general thinning of the muscles; from a much more recent muscular atrophy in one hand; [illegible]

CASE 2.—[illegible] three and three quarter [illegible] on Nov. 13th, 1903, [illegible] a healthy-looking and [illegible] internal viscera was [illegible] and eyes were normal. There was no nystagmus. Speech was natural. The spinal column showed a rounded prominence (antero-posterior curvature) in the lumbar region. Mr. McAdam Eccles did not think there was evidence of caries; probably, *therefore, this curvature had little to* do with the weakness of the legs. As regards the lower limbs there was no flatfoot; some slight stiffness at the ankle-joints was present; there was no definite loss of power of movement. The knee-jerks were increased on both sides; no ankle clonus was obtained. The plantar reflexes were of *the extensor type* on both sides. The gait was peculiar. The patient could walk alone but he kept his feet apart; he balanced with his arms as he walked and his feet seemed to stick to the ground. He did not cross his feet like his brother. The upper limbs were natural, except that Dr. Lewis Jones reported some weakness in the electrical reactions of the extensors of the wrists and fingers on both *sides. All the other muscles, both of* upper and lower limbs, reacted normally. The sensory functions were normal. There was no sphincter trouble. *According to* his mother the child had been born strong and healthy, though instruments were used at his birth. He began to walk when 11 months old. Ten months previously—i.e., when he was nearly three years old—she first noticed a weakness of the legs which had become worse gradually.

This patient, therefore, like his elder brother, had a difficulty of walking, with indications of a spastic paralysis (increased knee-jerks, extensor plantar *reflexes*), *but had no* deformities of the feet, no muscular atrophy in the upper limbs, unless the slight electrical abnormality noticed by Dr. *Lewis Jones be taken* as the herald of such atrophy, and no nystagmus.

CASE 3.—A third brother of this family, aged seven years, was thought by his mother to be weak on his legs and was brought to see me in the ward on Nov 27th, 1903. He also was a healthy looking child and as he walked with his boots on there was really nothing noticeable in his gait except perhaps a slight waddle and a slight unsteadiness when he turned, but in walking barefoot he seemed to turn his toes up and to bring his feet down rather heavily. There was no definite deformity of the feet or spinal curvature. The knee-jerks were well marked; ankle-jerks were obtained; no ankle clonus was present. The plantar reflexes were of extensor type. There was no affection of the upper limbs or nystagmus. It seemed probable that this boy suffered in a very slight degree from the same affection as his brothers.

The eldest of the family, a woman, aged 24 years, I saw at the same time. She had a very considerable spinal curvature in the dorsal region, mainly lateral, with convexity to the right, but perhaps some kyphosis as well. There was no deformity of the feet. The knee jerks were rather marked; ankle clonus was not present. The plantar reflexes, unfortunately, could not be obtained owing to the coldness of her feet. The hands were normal; the wrist-jerks were rather marked. Nystagmus was not present. She walked quite naturally, and indeed beyond the spinal curvature appeared to have nothing the matter with her. The whole family, according to her statements, consists of the following members: Father and mother, both alive and well; (1) daughter, aged 24 years (has spinal curvature); (2) son, aged 23 years (Case 1); (3) daughter, aged 18 years (said to be anæmic); (4) son, aged 17 years (said to be healthy); (5) son, aged 15 years (said to be healthy); (6) son, aged 13 years (said to be healthy); (7) daughter, aged 11 years (said to be healthy); (8) son (Case 3); (9) daughter, aged five or six years (said to be healthy); and (10) son, aged three and three-quarter years (Case 2).

I make the assumption that all three brothers had the same disease, differing only in degree. It is, however, rather difficult to fit the disease into any of the usual types of family paralysis. Friedreich's disease may be excluded. So may peroneal muscular atrophy (to which there was a certain *primâ facie* resemblance), by the presence of increased knee-jerks, of ankle clonus, and of extensor plantar reflexes. Amyotrophic lateral sclerosis, in which there occurs the combination of spastic paraplegia and muscular atrophy of the upper limbs, does not run in families and has a more rapid course than the disease under consideration. Syringomyelia, which sometimes occurs in more than one member of a family and which exhibits the same combination of spastic paraplegia with muscular atrophy, is characterised by sensory paralyses which here were not present. The condition of the legs might be explained by a cerebral diplegia, but the gradual development of the disease, the complete absence of mental affection, and, most of all, the muscular atrophy in the hand must weigh against this diagnosis. Dr. S. J. Gee, in St. Bartholomew's Hospital Reports for 1889, published three cases of "hereditary infantile spastic paraplegia" in a man and two of his children. The man had also muscular atrophy of the hands and one child had indications of commencing atrophy. These cases therefore strongly resembled my own. They differed, so far as my personal recollection goes (as medical registrar to the hospital I had the opportunity of seeing them), in that the spasticity of the lower limbs and the cross-legged progression in particular were much more marked. There was, too, much less paralysis of the atrophied hand muscles than in my Case 1, for whereas my patient could not do his work as a tailor, Dr. Gee's patient, also a tailor, was still the first hand in the shop.

Upper Wimpole-street, W.

A CASE OF FACIAL PARALYSIS ASSOCIATED WITH HERPES ZOSTER.

BY E. HEWAT FRASER, M.D., F.R.C.S. EDIN.

THE patient, a robust, middle-aged man, was seen on Oct. 20th, 1903 complaining of neuralgic pains in the face and head. On the 25th a widespread herpetic eruption appeared over the right side of the neck, spreading up on to the scalp and over the ear on to the lower part of the face; on the neck the rash extended down to the shoulder and over the clavicle on to the upper part of the chest. On Nov. 8th he was found to have developed typical Bell's paralysis of the affected side. The mouth was drawn to the left, the wrinkles had disappeared, and the actions of whistling and winking could not be performed; he also complained of the escape of food from between the teeth into the cheek of the paralysed side. No vesicles appeared on the upper part of the face but the skin was swollen and red and there was some conjunctivitis of the right eye. On mapping out the area of distribution of the herpes it was found to correspond to practically the whole region supplied by the superficial branches of the cervical plexus (second, third, and fourth cervical nerves), the ear and scalp in the area of supply of the great auricular and cervical nerves, the front of the neck in the region of the transverse cervical, and the lower neck, shoulder, and chest over the distribution of the suprasternal, supra-acromial, and supraclavicular branches being covered with herpetic vesicles. On the face the vesicles followed the distribution of the cutaneous branches of the inferior maxillary division of the fifth nerve. In regard to this it is of interest to note that the patient indicated with great accuracy the position of the mental foramen as a painful spot in describing his neuralgic pain. As regards the motor palsy this appeared to be restricted to the purely facial part of the seventh nerve supply. The occipital belly of the fronto-occipitalis was not paralysed. It was difficult to make out the condition of the platysma or of the retrahens and attollens aurem, but the facial muscles of expression were, as a whole, paralysed. No palsy of any of the muscles supplied by the fifth nerve could be made out. The neck muscles supplied by the cervical nerves appeared quite unaffected and the infrahyoid group supplied by the ansa hypoglossi, and so indirectly from the cervical nerves, was also uninjured. No drooping of the soft palate or uvula, such as has been described in cases of facial paralysis following herpes, was observed. On testing the special senses hearing was found to be quite unaffected, high- and low-pitched notes being quite readily appreciated on both sides. Taste was found to be decidedly dull on the affected side of the tongue. Tactile sense was markedly impaired all over the right side of the face and the tongue; compass points gave a single impression at a distance of six millimetres near the tip of the tongue on the right side but were recognised as separate at two millimetres on a corresponding point on the left. On the skin of the right cheek the points felt as one until a separation of one centimetre was reached. The temperature sense was unaffected. On Nov. 5th the patient had greatly improved and had almost regained control of the facial muscles, so that it seems likely that here, as in the majority of reported cases, complete recovery will ensue.

The association of paralysis of various muscles with herpetic eruptions is not uncommon. Many cases of facial palsy after herpes are on record, as is also paralysis of limb muscles—e.g., deltoid—after localised herpetic attacks, while Achard and Castaigne[1] report a case of permanent paralysis of the left pupil following herpes of the ophthalmic division of the fifth nerve. A curious point in the present case is the complete escape of the muscles supplied by the fifth and cervical nerves in contrast to the complete paralysis of the facial group. The absence of damage to the stapedius and to the muscles supplied early in the extracranial course of the seventh nerve (occipitalis, &c.) seems to show that the injury to this trunk was entirely peripheral in position. This may perhaps be explained by the spread of a neuritis along the numerous communicating branches from the fifth and cervical nerves to the seventh on the face. The tenderness at certain points of emergence of nerves noted above, seems to indicate the presence of some such inflamed condition of the trunks. In a somewhat similar case reported by Dr. A. S. Barnes[2] taste was lost on the affected side and hearing as regards high-pitched sounds was also impaired. Dr. Barnes therefore localised the injury to the facial nerve in the geniculate ganglion, thus explaining the paralysis of both the nerve to the stapedius and the chorda tympani. In the case now reported there was loss of taste but no change in the audibility of high notes, so then it seems probable that here the chorda became affected during its associated course with the lingual nerve. In another case recorded by Mr. H. A. Spencer[3] hearing and taste both escaped although there was complete facial paralysis, but the patient was a typical rheumatic subject and Mr. Spencer explained the condition as a simultaneous rheumatic neuritis of the facial and cervical nerves In the present case there were neither symptoms nor history of any rheumatic tendency The work of Campbell and Head[4] has definitely shown the cause of herpes zoster to lie in some damage to the Gasserian and posterior root ganglia as against the vascular theory advanced by Abadie,[5] so that in the present case one is forced to the conclusion that some lesion in the Gasserian and the second, third, and fourth cervical spinal ganglia set up a neuritis in the corresponding nerves *which spread by direct continuity to the terminal* distribution of the seventh nerve and so produced a temporary facial paralysis

AN EFFECTUAL MEANS OF DEALING WITH THE CONDITIONS OF CHRONIC OBSTRUCTION OF THE LARGE BOWEL

RESULTING FROM THE ADHESIONS WHICH DEVELOP IN CONSEQUENCE OF CHRONIC CONSTIPATION

BY W ARBUTHNOT LANE, M S LOND, F R C S ENG,
SURGEON TO GUY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND STREET

IN a lecture entitled "Chronic Obstruction of the Cæcum and Ascending Colon" published in THE LANCET of Jan 17th 1903 p 153, I called attention to the mechanical obstruction of the large bowel which arises in consequence of its being overloaded with contents My attention was directed to this diminution of the lumen, particularly of the hepatic flexure, by the close resemblance of the symptoms which are presented in these cases to those of renal troubles whether of calculus or of excessive mobility Before I recognised this condition I frequently cut down upon the right kidney expecting to find a stone and after carefully separating it and its pelvis from surrounding structures and exploring the organ have been much disappointed at finding nothing To my surprise, however, the patient frequently lost all pain and discomfort These experiences have occurred to many and are well recognised As soon as I became familiar with this state of cæcal obstruction I have called attention to I saw that the cases I had operated on as renal were really of this character and that the extensive separation of the colon from the kidney in the process of exploring that organ thoroughly was often sufficient to remove the obstruction, if not for ever, at all events for a time As the lecture may possibly have escaped the observation of the readers of this paper I will recapitulate briefly the details to which I refer

When fæcal matter is allowed to accumulate in the intestinal tract there are two portions which are particularly likely to suffer and to become more or less inflamed from the irritation which its presence in excessive bulk or in excessive hardness produces They are the cæcum and ascending colon and the sigmoid flexure The splenic flexure is less commonly affected The segment which is most affected is formed by the cæcum and the ascending colon This part of the large bowel is the natural cesspool of the tract, material being collected in it, and in the recumbent position the overflow passes along the transverse colon usually without any difficulty When the trunk is in a position other than the supine there is required for the expulsion of the contents of the cesspool the expenditure of an amount of energy often in excess of that which the organism can afford, and as there is no obstruction to the passage of liquid from the ileum into the cæcum the distension of the cesspool and the weight of its contents become considerable In consequence of this its walls become inflamed to a certain extent and peritoneal adhesions form between it and the adjacent wall of the abdomen externally These adhesions oppose the downward and inward displacement of the loaded cæcum As time goes on these adhesions form above an omentum of considerable strength which having an attachment in the right flank above and external to the kidney, is distributed over the anterior and outer surface of the hepatic flexure and ascending colon and affords an excellent means of supporting and slinging this overloaded bowel in the erect position The arrangement is such, however, that while the erect posture is maintained there is an abrupt kink of the bowel in the situation of the hepatic flexure The adhesions which bind down the cæcum externally also fix the proximal half of the appendix In consequence of the fixation of this portion of the appendix distension of the cesspool is associated of *necessity* with an abrupt *kink of the appendix* at about its centre and with a coincident distension of the distal half of this structure which may produce all the very varying symptoms of what is called "appendicitis The emptying of the distended cæcum in the ordinary course of events relaxes the traction on the adhesions and may so permit of the escape of the dammed up contents of the distal portion of the appendix We are all very familiar clinically with the fact that symptoms of appendical irritation may subside at once after the intestines have been thoroughly evacuated by a purge

The formation of adhesions between the cæcum, the ascending colon, and the abdominal wall serves not only to support the overloaded cæcum but also to prevent its displacement upwards and inwards and the formation of a so called volvulus Though this condition is described as a volvulus and is put on a par with volvulus of the sigmoid flexure the conditions are quite different In the case of the cæcum and the ascending colon what is called a volvulus is merely the obstruction of the large bowel by the constriction of the hepatic flexure by the adhesions and omentum I have described The cesspool, over distended with its contents, moves in the direction of least resistance along a radius formed by the new mesentery which is downwards, inwards upwards, and forwards When seen in this position the distension of the cæcum is regarded as being brought about by the twist or volvulus, whereas the position of the overfull bowel in the situation of the volvulus is the natural and necessary sequence of obstruction of the flexure and an insufficient anchoring of the cæcum to the abdominal wall externally The obstruction of the hepatic flexure by adhesions and by the acquired mesentery which results from their presence is so remarkable and characteristic that one wonders how it escaped one's observation before

I soon became alive to the fact that the symptoms which arise in consequence of the obstruction of the bowel at the hepatic flexure were usually attributed to inflammation of the appendix which is naturally often associated with it The presence of adhesions about the proximal half of the appendix brought support to this view Consequently many cases came under my observation in which symptoms persevered unchanged after the removal of the appendix much to the disappointment of the patient and of the surgeon who operated On exploring them I found that precisely the same conditions of mechanical obstruction by band and adhesion existed in them all and that the symptoms were only relieved by the division of these bands and by insuring the subsequent efficient action of the bowel by purges, by massage or by exercise

In spite however of the thorough division of bands, adhesions, and the complete liberation of the cæcum and ascending colon from the constricting influence exerted by them I came across a certain percentage of cases in which the operation produced only a temporary cessation of the symptoms of obstruction, the old trouble reappearing very soon after This was the case especially in women who were physically feeble who suffered from respiratory incapacity and whose functions generally were performed in a *correspondingly* unsatisfactory manner An examination of their intestines at the time of the operation showed them to be flaccid and plastic retaining for an appreciable time the form and position in which they were placed by the fingers At first I attempted to avoid the re formation of adhesions by the administration of powerful purges before or immediately after the operation placing the patient on the left side, and by other methods I could think of Yet in a certain and by no means a small proportion of cases these efforts were unavailing Being of opinion that the harm to the individual, both as regards pain and the formation of ptomaines &c, consequent on the tedious passage of fæces through the large bowel, was greater than any advantage gained by absorption in that tract I determined to exclude the greater part of the large bowel from taking any share in the scheme of digestion I knew that the ileum had been connected with the sigmoid flexure or with the upper part of the rectum to deal with various troubles arising in special and rare cases, such as cancer, obstinate atony of the colon, intussusception, fistulæ, and the like, and that the result had been excellent so far as the nutrition of the patient was concerned. In these circumstances I determined to employ this method as a routine treatment in the definite group of cases of obstruction of the intestine produced by adhesions and by an acquired omentum in which the complete division of these constricting media will not afford relief, the recurrence or continuance of symptoms being produced by their re-formation. I make a very free lateral anastomosis between the lower limit of the ileum and the upper part of the rectum, or the sigmoid flexure if the rectum is too bound by fixation of the sigmoid flexure to allow of its being readily handled. For this purpose an efficient anastomosis can only be made by sacrificing a portion of the circumferences of both ileum and large bowel sufficient to insure that the resulting lumen at the junction shall not exceed the original size of the large bowel. The result of such operative treatment has been very satisfactory, the patient being freed from pain and tenderness, losing the dirty colour and inactivity consequent on the absorption of ptomaines, improving in weight, and obtaining regular daily evacuations by means of mild purgatives. The only objection to the lateral anastomosis is that the presence of any very large quantity of solid fæcal matter in the vicinity of the opening in the large bowel may possibly cause fæces to pass on into the cæcum. For this reason I now divide the ileum, closing its distal aperture and making its proximal section open into the lower end of the large bowel, so rendering it impossible for any material to enter the cæcum.

Cavendish-square, W.

ON THE ACTION OF VENOMS OF DIFFERENT SPECIES OF POISONOUS SNAKES ON THE NERVOUS SYSTEM.

BY GEORGE LAMB, M.D. GLASG.,
CAPTAIN, I.M.S.;
AND
WALTER K. HUNTER, M.D., D.SC. GLASG.,
ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; LECTURER IN PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW.

Preliminary Account: Cobra Venom.

IT is admitted by all workers, both of earlier date and those of more recent times, that snake venoms in general do seriously affect the nervous system. There has been, however, considerable dispute as to the manner in which the action is brought about and as to the exact part which this action plays in causing the symptoms and the fatal result in cases of snake venom intoxication. Thus, while nearly every writer who has specially studied the physiological action of cobra venom considers that that poison owes its lethal properties principally, if not entirely, to a direct action on the nervous system, Cunningham[1] contends that its primary action is on the blood and that the nervous symptoms which are observed in cobra venom intoxication are wholly dependent on the action of the poison on the blood. Again, this same observer,[2] as a result of his experiments with the venom of daboia Russellii, puts forward the opinion that when this poison causes rapid death it does so entirely by a direct action on the central nervous system. He looks upon its primary action as being that of a strong nerve irritant. It is not our intention in this preliminary account to enter into the discussion of this latter problem. One of us[3] has already put forward facts which proved the inaccuracy of Cunningham's hypothesis and which showed beyond a doubt that all rapid deaths the result of the injection of daboia venom were due to a more or less extensive intravascular thrombosis. The observations, in short, recorded in that paper and in another communication[4] of later date showed that daboia venom had a marked action on the blood plasma and on the red blood cells, but they did not show that it had no action on the nervous system. To this point, however, we shall return in another communication. From these few considerations alone, and they might be greatly multiplied, it would appear that renewed research is necessary with a view of trying to determine definitely the action of the venoms of different species of snakes on the central and peripheral nervous systems. Up to the present time this problem has been approached by all workers, with few exceptions, from one standpoint only—viz., the standpoint of the observation of the symptoms which result from injections of the various venoms and the observation of gross pathological appearances in fatal cases. Such a method of research as a means of determining the exact physiological action of a poison on the nervous system is surrounded with difficulties. These difficulties have been well stated by Martin[5] of Melbourne as follows: "The determination of the exact physiological action of a poison on the nervous system of the higher animals is always difficult. The difficulties are enormously increased when the poison, as is the case with most snake venoms, profoundly affects the blood and the whole circulatory apparatus also. In such a case it is not easy to distinguish effects which are due to the primary action of the poison on nervous tissue from those which are secondary to changes produced on the circulation and blood." It was therefore necessary to approach this question from another direction.

One of the exceptions to which we have referred above consists in an observation made by Dr. B. Kilvington,[6] working in Professor Martin's laboratory at Melbourne—viz., that the venom of the Australian tiger snake produces marked chromatolysis of the Nissl granules of the cells in at least one portion of the nervous system if the animal survives the injection of the poison for over three hours. Only one part of the nervous system, however, was selected for examination by this worker—viz., the cervical enlargement of the cord. The method which we have adopted was to combine the observation of the symptoms during life with histological examinations of portions of tissue taken from all parts of the central nervous system and from the peripheral nerves of animals, principally monkeys, which had received injections of the venom of a certain species of snake and which had died at varying intervals after these injections. It was thought that by following this method of investigation a definite opinion could be arrived at as to whether there was a direct action of the poison on the nervous system and also as to whether in those cases in which evidence of a direct action was present any relationship could be established between the symptoms observed and the histological appearances seen in the central nervous system and in the peripheral nerves. In this way we are investigating the venoms of several of the most deadly of the Indian snakes, among these being naia tripudians (cobra), daboia Russellii (chain viper), bungarus fasciatus (banded krait), and echis carinata (phoorsa). In the course of this investigation many interesting and important points have turned up which may throw light on other neuro-pathological conditions and which make it necessary that further research should be made along the lines we have indicated.

In this preliminary account we propose to deal with only one variety of snake venom and to leave over for future communications the observations made with the other poisons. Moreover, after further investigation we shall be in a better position to sift completely the data we have obtained and to show their bearing on the action of neuro-trophic poisons in general. The material which was used in all the experiments was pure, dry, and fresh poison. This was collected under the personal supervision of one of us during a period of several months from a number of healthy living snakes. The poison was obtained either by squeezing the glands or by allowing the snakes to bite through a sheet of waterproof cloth tightly stretched over the mouth of a stout wineglass. When the poison had been thoroughly desiccated over lime it was added to the general stock which was preserved in an air-tight tube kept from the light. Before the venom was weighed it was reduced to an impalpable powder and again dried over lime.

[6] Journal of Physiology, vol. xxviii., No. 6, Dec. 15th, 1902.

The physiological action of cobra venom and the symptoms of the intoxication produced by it have been studied by many observers, especially in India. Nearly all these workers—Fayrer, Brunton, the members of the Indian commission, Wall, Aron, and Calmette—hold that cobra venom is a primary neurotic poison, acting directly upon the nervous, and especially the central nervous, system. This opinion, however, has only been arrived at by the observation of the symptoms which follow an injection of this venom. These symptoms certainly point, as we shall see, to an action of the poison on the nervous system. While this is the general opinion Cunningham, as we have mentioned above, has put forward the hypothesis that the primary action of cobra venom is an action on the blood and that the nervous symptoms, which have been observed and described by all alike, are dependent on, and can be interpreted by, the effects which the poison has on the blood. He holds that there is no satisfactory evidence that cobra venom has a primary action on the nervous system and he asks *for more direct proof of this hypothesis* than has hitherto been advanced. We hope in this communication to furnish sufficient direct proof of the effect of the action of this venom on the nervous system. As the symptoms of cobra-venom intoxication both in man and in animals are well known, having been described accurately by various Indian observers, it is unnecessary for us to enter into these symptoms in any detail. The following, therefore, is only a short summary taken from the data of the observations of one of us who has had the opportunity of studying the symptoms in two actual cases of cobra bite in man and in several hundred experiments in animals, including monkeys, horses, donkeys, dogs, &c.

When a large quantity of cobra venom is injected directly into the blood stream of an animal death takes place within three or four minutes after the injection. As a rule muscular twitchings and general convulsions are the only symptoms which are observed to precede death in these cases. On post mortem examination the blood is found to be liquid throughout; there is no trace of intravascular clotting to be found anywhere. If the quantity of poison injected intravenously approaches the minimum lethal dose the symptoms observed are the same as when the injection is made subcutaneously, the only difference being that they are of more rapid onset and terminate more quickly in death than in the latter case.

The first constitutional symptom which is observed to follow a subcutaneous injection of cobra venom is a state of lethargy and drowsiness. The head is seen to fall forward, almost immediately to be recovered with a jerk. The eyes are kept half shut but are opened suddenly on any stimulation. It is to be noted that there is no preliminary stage of excitement. Then paresis of the extremities becomes apparent and this is more marked at first in the hind limbs than in the fore-limbs; the animal has difficulty in moving and if a monkey it is seen to catch the bars of its cage to prevent itself from falling down. In man paralysis of the tongue and muscles of the throat soon makes itself evident; there is loss of the power of speech and the saliva which is profusely secreted trickles down the lip. Nausea, vomiting, and retching are common symptoms in man and in dogs. The paralysis rapidly advances, becoming more general and more marked. The animal soon lies down unable to move. The breathing still continues, although it may be slow and with much inspiratory effort. Just as the respiration ceases general convulsions may set in and close the scene This symptom, however, is not observed in all cases. If the chest be opened immediately after the respiration has ceased the heart is seen to be still beating regularly and pulsation may go on for from 20 minutes to half an hour after respiration has stopped. On post-mortem examination no gross lesions of any kind are to be found. In those cases in which death has been at all delayed or in which a large quantity of venom has been injected directly into the blood stream the coagulability of the blood is found to be diminished. No other pathological condition is apparent. We have mentioned above that Cunningham considers that the symptoms which we have just narrated are dependent for their cause on the action of the poison on the blood. Now the action of cobra venom on the blood cells and on the blood plasma has been fully investigated by one of us.[7]

The conclusions arrived at from this investigation were: (1) that cobra venom has a marked hæmolytic action but that the effects of this action *in vivo* were of little or no importance in the production of the constitutional symptoms; and (2) that cobra venom causes a certain but by no means well-marked diminution of the blood coagulability and that no symptoms as a rule result from this deficiency of blood coagulability. It is evident, therefore, that Cunningham's hypothesis is by no means an adequate explanation as a cause of the symptoms and of the fatal result in these cases and that we have still to search for other pathological lesions which might account for them. With this end in view we have examined the nervous systems of the following animals which died after having received injections of cobra venom:—

—	Weight in grammes.	Dose per kilogramme.	Time before death.	
		Milligrammes.	Hrs.	Mins.
Monkey No. 1	1830	0 25, subcutaneously.	6	0
,, ,, 2	3110	0 5, ,,	2	45
,, ,, 3	2770	0 5, ,,	2	30
,, ,, 4	2200	3·0, ,,	1	10
,, ,, 5	2050	10 0, intravenously.	0	3½
,, ,, 6	1900	10 0, ,,	0	2½
Rat ,, 1	—	0 25, subcutaneously. (+antivenomous serum)	45	0
,, ,, 2	—	0 05, subcutaneously.	20	0
,, ,, 3	—	0 25, ,,	3	0

The methods which were adopted for the histological examination of the nervous systems of these animals were as follows. Shortly after death portions of the cerebral cortex and cerebellum, the medulla, the pons, and pieces from different levels of the cord, as well as portions of the median, posterior tibial, and vagus nerves, were removed. Some of these pieces were fixed either in saturated solution of perchloride of mercury or in formol (10 per cent), and then mounted in paraffin.[8] Portions of the same tissues from four normal control monkeys were treated in a similar manner. This portion of the work was done by one of us in India. The paraffin blocks were sent home and sections were then cut, examined, and described by the collaborator. The staining of the tissues was according to Nissl's method either by theonine or toluidin blue. Some sections were also stained with hæmatoxylin and eosine. The following is a description of the changes observed in the nervous system in each case.

Monkey No. 1, weight 1830 grammes, died in six hours after subcutaneous injection of 0 25 milligramme per kilogramme of cobra venom. Throughout the cord the appearances are somewhat striking. In the cervical enlargement, at the periphery of each anterior horn—i e, in the antero- and postero-lateral groups—some ten to 15 cells are to be seen with well-stained and fairly well-defined Nissl granules. These granules, however, are not quite normal, for though not definitely fragmented they look as if little pieces had been clipped off their edges and under a high power it is quite apparent that their outlines are blurred and ill-defined as if some solvent had been acting on them. The rest of the cells in the anterior horn are degenerated and without any granules whatever. They are not typical "ghost cells," their nucleus and reticulum being too deeply stained for that; they look, rather, like a normal cell minus its chromatic granules. No cell is to be seen with the dust-like granulation so characteristic of a more chronic chromatolysis. In the lumbo-sacral region the same appearances are met with as in the cervical enlargement, though the number of these almost normal cells is less and a fair proportion of "ghost cells" is present along with the deeper stained cells with no granules. In almost all the cells the nucleus is central and the nucleolus distinct.

In the pons and the medulla the changes are much the same as in the cord, though not so marked. The twelfth, tenth (motor), and seventh nuclei all contain some of the almost normal cells, but also a considerable proportion of cells with the Nissl bodies much broken up. The cells of the seventh nucleus are less affected than those of the other two nuclei. In the cortex the vast majority of the pyramidal cells show an acute chromatolysis. As in the cord, there are some cells well stained and with their granules but little altered; but these are few and far between, not more than three or four to each section. In the cerebellum not one normal Purkinje cell is to be seen, most being deeply and diffusely stained, with a few dust-like granules in their plasma. The vessels throughout the cord, pons, medulla, and cortex are considerably dilated and in the cord some small hæmorrhages into the grey matter are to be seen. There is possibly a slight increase in the connective-tissue cells. These seem to be attracted by the ganglion cells, for one frequently sees such a cell with three or four connective-tissue cells around it and in close apposition to it In the peripheral nerves there seems to be a slight increase of the internodal nuclei, but this is not by any means well marked.

---

[7] Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. New Series. 1903. No. 4.

[8] Other pieces of the same tissues were hardened in Müller's fluid and then passed through Marc[illegible] paraffin But owing to some bl[illegible] it was decided that the osmic ac[illegible] A note of this will be given in a [illegible]

Monkey No. 2, weight 3110 grammes. This animal received subcutaneously 0·4 milligramme per kilogramme of venom which had been kept in solution for some days. After the injection there were marked symptoms of poisoning but the animal recovered. Three days afterwards a second injection of 0·5 milligramme of poison freshly dissolved was given and death supervened in two and three quarter hours. The appearances in the cord seem somewhat different at different levels, some sections being practically normal, while others show quite a proportion of altered cells. Taken as a whole, there seems little doubt of the presence of degenerative changes, but they are not so well marked as in Monkey 1 As in that animal, there are cells with their granules slightly fragmented and others with almost no granules at all. The changes are most marked in the cells lying towards the central canal. The pons and medulla are almost normal. In the cerebral and cerebellar centres the cells are almost entirely devoid of granulation and the degenerative changes are just about as well marked as in Monkey 1. There is very slight increase, if any, in the nuclei of the peripheral nerves.

Monkey No. 3, weight 2770 grammes, died in two and a half hours after subcutaneous injection of 0·5 milligramme per kilogramme of cobra venom. In the cord the vast majority of the lateral cells seem practically normal, though they are, perhaps, rather more diffusely stained than they should be and their granules are possibly a little bit fragmented. Passing inwards there are cells found with more definite fragmentation and some have little granulation at all. The pons and medulla are normal. The cells of the cerebral cortex also are but little altered and may be considered as almost normal. The nerves show no abnormality.

Monkey No. 4, weight 2200 grammes, died in one hour and ten minutes after subcutaneous injection of 3·0 milligrammes per kilogramme of cobra venom. In the cord the vast majority of the cells seem quite normal, there being but a small proportion with their granules dissolved out. This may, however, be a commencing degeneration but if so it is not unequivocal. The cells of the pons, medulla, and cortex are almost normal. In the cerebellum the Purkinje cells are too diffusely stained and seem deficient in granules. The nerves seem little altered.

Monkey No. 5, weight 2050 grammes, died in three and a half minutes after intravenous injection of 10 milligrammes per kilogramme of cobra venom. The appearances throughout the nervous system may be considered normal.

Monkey No. 6, weight 1900 grammes, died in two and a half minutes after intravenous injection of 10 milligrammes per kilogramme of cobra venom The appearances are as in Monkey No. 5.

Rat No. 1 died in 45 hours after subcutaneous injection of 0·25 milligramme of cobra venom plus antivenomous serum The degenerative changes in the cortex, pons, medulla, and cord are extreme. The cells are deeply stained but they are much broken up and vacuolated. Some have pieces punched out of their edges, giving them an irregular and ragged outline. Almost none of these cells has any granulation whatever. There seems no doubt that in the majority of the cells their achromatic part is involved and that they are beyond recovery.

Rat No 2 died in 20 hours after subcutaneous injection of 0·05 milligramme of cobra venom. In the cord not a normal ganglion cell is to be found. Most of the cells are faintly stained with no granules and with a diffusely stained light blue nucleus and some cells have no nucleus at all. Other cells, again, are rather more deeply stained and contain broken up granules. There is no vacuolation to be seen. The appearances in the cortex and medulla are much the same as in the cord.

Rat No 3 died in three hours after subcutaneous injection of 0·25 milligramme of cobra venom. In this case there is quite a proportion of normal cells but, on the other hand, the majority of the cells show definite degenerative changes. In place of the pale cells of Rat 2 we have deeper staining, some cells having fragmented granules, and some no granules whatever. A few cells are very much disintegrated and vacuolated. In most cells the nucleus is central but it is rather ill-defined and diffusely stained. The degenerative changes are even more marked than in Monkey 1 (which died after six hours) and much more marked than in Monkeys 2 and 3, each of which died in rather less than three hours after injection, about the same time as this rat.

We see, then, that in cobra poisoning we have a toxic substance which when injected subcutaneously produces symptoms of muscle paralysis and that when we examine the nervous mechanism which controls these paralysed muscles there is found to be evidence of such degenerative changes as are known to be so frequently associated with paralysis. It seems fairly certain, therefore, that cobra venom has a direct action on the motor neurones. Doubtless this toxin, like most other toxic substances, has also a poisonous action on all the tissues of the body, but with such evidence as we have before us we cannot but conclude that it has a specially selective action on the nervous system and that it is from this that death results. There can be no reason, therefore, to ascribe, as Cunningham did, the cobra poisoning symptoms to blood changes which, even apart from the proof now furnished to the contrary, could not, as one of us has shown, account for them. Certainly not all the animals killed with the venom showed histological changes in the nervous system, for it would seem that time is required for these to develop. And here we would note that in such animals as Monkeys 3, 4, 5, and 6 we have had some difficulty in knowing how to interpret the slight changes found in some of their ganglion cells—whether to call them variations within the limits of what may be normal or to count them as evidence of an early degeneration. There can be no absolute standard to go by, for even in our four control monkeys a certain proportion of the ganglion cells were not without changes in their Nissl granules, and when we are dealing with the very earliest appearances of degeneration it must be difficult to know where to draw the line between what is normal and what is degeneration We have had this in mind in recording our cases and have described equivocal cases as being normal rather than make the error of finding evidence of degeneration where it does not exist. The degenerative changes in Monkey 1 (dead after six hours) were undoubted. In Monkey 2 (dead after two and three-quarter hours) and Monkey 3 (dead after two and a half hours) the appearances, though not so certain, may quite fairly be taken as showing an early degeneration. Monkey 4 (dead in one and one-sixth hours) is doubtful. Monkeys 5 and 6 (dead in a few minutes) may be considered normal. So that it would seem that two, and possibly three, hours are required to elapse after the injection of the venom before degenerative changes appear in these monkeys' cells. With the rat the time might be less, for in Rat 3 (dead after three hours) the degenerative changes were more marked than even in Monkey 1 (dead after six hours). Possibly the cells of the rat are not so stable as those of the monkey, but in any case one is never so sure of the results obtained in the smaller animals and we mean to deal with monkeys only in the future. One other point we wish to draw attention to is that in the six monkeys dying with cobra poisoning the staining of their ganglion cells was much more intense than that in the four control animals. This may be an accident, but we had to recognise the fact that in decolourising the section the length of time which was required was longer in the monkeys subjected to cobra poisoning than in the normal ones. This may, as we say, be an accident of fixing or staining, but we are disposed to regard it as due to the cobra venom producing some chemical change in the cells themselves.

In concluding, we wish to express our indebtedness to Dr. J. Lindsay Steven for the use of his laboratory and apparatus in carrying out a part of this investigation.

SOME OBSERVATIONS REGARDING THE SPECIAL CIRCUMSTANCES OF CASES OF LEAD POISONING OCCURRING AMONGST WORKERS IN WHITE-LEAD FACTORIES.

By *THEODORE A. W. OGG, L.R.C.P., L.R.C.S. Edin.*,
L.F.P.S. Glasg.

THE circumstances influencing workers in white-lead factories vary considerably and may be regarded from the point of view of the workers themselves, their susceptibility to the action of the metal and also to the processes employed in the different departments of the works, and the special work undertaken by them. With regard to the susceptibility of the different workers this also varies considerably, so much depending on the habits of the worker, his attention to personal hygiene and his strict observance of the necessary precautions required in all white-lead factories that it is very difficult, and only after taking all these circumstances into consideration, to arrive at anything like a satisfactory conclusion. Some workers more than others seem to have something like immunity to the action of lead, and it would appear that in those cases after having imbibed a certain quantity of it into their systems they might work for long periods without becoming further susceptible to its action. Those cases are usually seen in well-developed, healthy, and temperate workers, who recognise the ordinary duties of health and the precautionary measures adopted at the works. That the latter have in some degree to do with this immunity is undoubted, yet others who observe the same precautions become victims. One instance of this was seen where the person had been employed in the works for over 40 years. Although decidedly anæmic he showed none of the symptoms which might have been expected after being employed for this period of time in a lead factory. So far as I could ascertain, he was a steady, temperate workman and careful as to his personal hygiene and the factory regulations.

Many of these workpeople come from the lowest classes and to persuade them to give attention to the crudest laws of personal hygiene is a very difficult matter indeed. Many are prone to excess, many subsist on a dietary of tea and bread with an almost total exclusion of fresh fruit and vegetables. It is no wonder then, that impaired nutrition plays such an important rôle in incipient lead poisoning. The worker thus when idle has only the barest subsistence and after a period of suspension it may be he returns to work with his health at a very low ebb, soon to find himself again the victim of plumbism.

An example of this is seen in the following case. A woman was suspended for three months from work in August as suffering from colic, constipation, and vomiting. During her suspension she had vomited on one or two occasions. She returned to work on March 9th following (seven months later) and had been working for one and three-quarter days in the white-lead department when she was seized with a convulsion at the factory which was followed by three others while she was being conveyed to her home in a cab. There was no previous history of epilepsy. She acknowledged, however, having worked for the one and three-quarter days without using a respirator.

As a rule anæmic young men and women are less resistant, judging from the frequency with which they are attacked. Men are less careful during work than women and are equally susceptible. I have never seen sufficient evidence to cause me to think that women were more susceptible than men. The greatest difficulty in the works was to get the employés to attend to the rules of the factory and amongst [illegible] drinks provided for them. Any [illegible] was eschewed by them. Sulphur [illegible]troduced and taken more readily. The period at which a good many showed symptoms of dyspepsia and constipation followed by colic was about six weeks after their commencing to work. This, however, varied and depended partly on the special employment of the workpeople. In the preparation of the carbonate of lead where the Dutch process was used—in which the lead in thin sheets is placed on the top of pots filled with acetic acid and is converted first into the subacetate and finally decomposed by carbon dioxide emitted from tan—the cases were most numerous. Over two-thirds of my cases occurred in this department. It is easy to understand how this should be so. The carbonate which is removed from the stacks (superimposed layers of pots, lead, and tan) by being either carried in trays on the heads of the workers or by machinery (hydraulic cranes) is placed in trolleys to be conveyed to the rolling mills. A cloud of white-lead dust is easily caused to ascend among the workers by careless handling of the lead and especially so when the carbonate has not been properly watered or moistened before removal from the stack. Indeed, where the removal is done by machinery, although fewer workpeople are required, the process is in itself more dangerous as the buckets containing the lead can be lifted and deposited in a more careful manner by the hand. A great deal, therefore, depends upon the way in which the workpeople handle the lead and in this they are often attentive at first but get hardened by association with less careful workers.

A large percentage of my cases from this part of the works presented symptoms of epilepsy, some, indeed, without minor symptoms appearing first, showing, no doubt, that the lead had gained entrance into the system in large quantities, and evidently cases of acute poisoning. Were these cases not also due to the entrance of the poison into the system through the respiratory tract? The facts pointed to this. Indeed, the respiratory tract is perhaps a more potent source than is usually considered, not perhaps in all parts of the works, but certainly in the departments where dust is prevalent. The ordinary respirator worn by the workpeople does not exclude this and a thoroughly good and serviceable respirator has yet to be devised.

Those who worked in the drying chambers, where the temperature was often very high (200° F.), were also frequent victims and after a short time they were usually transferred to less dangerous parts. The smallest number of cases came from the grinding and smelting departments, where wet grinding was carried on. In the red-lead department not more than from 1 to 2 per cent. of cases occurred. The removal of the carbonate from the stacks caused by far the largest percentage of cases and was obviously the most dangerous part of the work, but the suppression of the dust would have made it less so.

Smoking was prohibited in the works but chewing which is less easily detected, was more practised by the workers. This is one of the ways by which large quantities of lead may gain entrance into the system by the digestive tract. The workman whose hands are covered with white-lead twists off enough tobacco, which in turn gets covered with the white lead, and this he places in his mouth. In glancing down a file of workers who were being presented for examination I have seen one or two chewing when they thought they were unobserved, but when charged with it they would deny and when asked to open the mouth they would previously swallow the tobacco in order to escape detection.

Such are instances of some of the difficulties to be met with in dealing with workers who use every means to prevent information being conveyed to the officials that would endanger their future employment and to impose too strict limitations—e.g., to exclude all who are addicted to the abuse of alcohol in these works—would be a very difficult measure indeed to carry into operation. The remedy which would lead to a diminution of the cases of saturnine intoxication amongst white-lead workers seems to lie in the strict observance of the precautionary or preventive measures adopted in these works, in some means by which the quantity of dust in certain departments would be lessened, and to the suspension from work of cases presenting *early* symptoms at the periodical medical examinations as well as the necessity for *each* worker being medically examined and certified fit for work, at intervals of perhaps a week before being employed. This would tend to prevent employés escaping examination by being absent, wilfully or otherwise, on the day of the visit of the medical officer to the factory.

◆

A CASE OF ASCITES RAPIDLY CURED ON THE ADMINISTRATION OF IODIDE OF POTASSIUM.

BY JOSEPH A. W. PEREIRA, M D BRUX., L.R.C.P. LOND., M.R C S ENG.,
MEDICAL OFFICER, EXETER CITY WORKHOUSE.

A MAN, 25 years of age, was admitted into the Exeter City Workhouse Infirmary on Dec. 28th, 1901. His condition was as follows. The abdomen was distended with fluid. The urine was scanty, high coloured, and showed a distinct trace of albumin. The liver did not seem to be enlarged; its edge could not be felt. There was no jaundice. The heart was displaced upwards and its sounds, though feeble, presented no murmur. There was no œdema about the eyelids, the thorax, or the upper or lower extremities. The face was not emaciated, neither was the complexion anæmic. The man was ordered a drachm of compound jalap powder every alternate morning and a mixture of digitalis, squills, and broom was prescribed. He took his discharge on Feb. 25th, the ascites being slightly more pronounced than on his admission He returned to the infirmary on March 3rd, 1902. His condition was greatly aggravated and, moreover, his lower limbs, his scrotum, and penis were very œdematous.

For a case like this tapping the abdomen is the recognised treatment. But there were certain noteworthy features in the case. The patient was under the age at which alcoholic cirrhosis is generally seen. He had not the hepatic facies of the tippler. His physical strength too, was remarkable, for he actually walked to the infirmary, a distance of nearly a mile. He presented none of the toxæmic symptoms which one would have expected in ascites of such a grade. The conclusion I came to was that there was pressure on some abdominal vein or veins, possibly the portal, which caused the ascites. All the other signs and symptoms were the natural consequences of the pressure. In a man of his age a gumma was the most probable cause and on this supposition I placed him on 7½-grain doses of iodide of potassium three times a day. The effect of the drug was that of a powerful diuretic. The urine became copious and free from albumin. He took his discharge on April 29th, without a trace of ascites or œdema anywhere. He is at the present moment earning his living as a labourer. I record this case because it is rare for ascites, from whatever cause arising, to disappear completely. It is also the most remarkable one in my experience of the effect of a single drug on a disease, for this man whose heart was very seriously embarrassed by reason of the great abdominal distension left the infirmary within two months perfectly well. It also presented features which, as I have shown above, differentiated it from alcoholic cirrhosis of the liver in which the iodide of potassium would have been useless.

Exeter.

A CASE OF POISONING WITH HYOSCINE HYDROBROMATE.

BY J. C. M. GIVEN, M.D., M.R.C.P. LOND.

ON Oct. 30th, 1903, a man, aged 69 years, came to me complaining of cramps in the muscles of the legs at night and also of senile tremor of the hands. He had been under my care at intervals for several years. Five years ago I attended him through a severe attack of basic pneumonia which was accompanied by much excitement, and then $\frac{1}{100}$th of a grain of hyoscine hydrobromate was used hypodermically with great benefit. At the present time he was in fair health for his age. The pulse was rather quick—about 90 per minute. The heart sounds were normal. The urine was high coloured; it was free from albumin and sugar. I ordered him $\frac{1}{200}$th of a grain of hyoscine hydrobromate in one drachm of water to be taken at bedtime. At 9.45 P.M. on the same day I was hurriedly summoned to see him. I was informed that at 9 15 P.M. one teaspoonful of the medicine was given him by his son (this was confirmed by the amount absent from the bottle). After swallowing it he undressed and got into bed. While undressing he remarked to his wife that his throat felt very dry and she noticed that his speech was rather thick. Two or three minutes after he got into bed his wife heard him breathing very deeply; she tried to rouse him but could not and sent for me. I found him half an hour after he had taken the medicine deeply comatose with stertorous breathing and flushed face. His pulse was 80 per minute and regular. his pupils were dilated and equal, and the conjunctival reflex was very slight; I could not rouse him by any means. I injected $\frac{1}{10}$th of a grain of strychnine hypodermically and gave one ounce of brandy by the rectum. At 10.45 P.M. there was no improvement; the coma if anything was deeper, the conjunctival reflex was quite absent, the pulse was smaller and weaker, and there was some twitching of the arms and legs. I sent for my syphon stomach-tube and for Dr. W. B. Paterson to help me. In the meantime I injected $\frac{1}{4}$th of a grain of morphine with one grain of caffeine citrate. In a few minutes the pupils became less dilated but otherwise there was no change. At 11.45 P.M., with Dr. Paterson's assistance, I washed out the stomach by the syphon tube with hot water, removing a small quantity of partially digested food, and then passed into the stomach about eight ounces of strong black coffee and one ounce of brandy. At 1 A.M. the conjunctival reflex began to return and the patient flinched on pinching the skin on the inner side of the arm. Improvement slowly set in, the breathing became less noisy, and the pulse fuller and stronger. At 3 A.M. he could be partially roused for a moment by pinching and shouting but at once relapsed into a somnolent condition; the pupils now reacted to light. At 5 A.M. he made an attempt to speak and swallowed some coffee. At 8 A M., that is 11 hours after taking the dose, he was really conscious and able to speak for the first time and he thenceforth made an uneventful recovery.

The prescription, which was for $\frac{1}{200}$th of a grain of hyoscine hydrobromate in one drachm of water with orders to send two ounces, was dispensed at a very trustworthy druggist's, and a very unfortunate and dangerous, though instructive, mistake was made in dispensing it. The druggists in question gave me, I am glad to say, every facility for investigating the matter. It appears that they had two establishments; at the one to which the prescription was taken they had no hyoscine in stock, so the dispenser sent a written message to the other place for 0 08 gr. of hyoscine hydrobromate in two ounces of water, which is equal to $\frac{16}{200}$ths of a grain, the exact amount he required for the whole bottle of medicine; the dispenser at the second shop, seeing that decimals were used, took it for granted that it was a foreign prescription and that "gr." stood for grammes and sent 0·08 gramme which the first man sent to my patient. The result of this was that he got more than 15 times as much as was intended, or about $\frac{1}{13}$th of a grain. This appears to be a good object lesson in the danger of the present condition of weights and measures in the Pharmacopœia, where it is now optional for either the decimal system or the apothecaries' measure to be used. Surely the time has come for the rational and scientific metric system to be enforced as the officinal standard.

The literature of hyoscine poisoning seems to be scanty and points to the fact that the drug is rather uncertain in its action, sometimes producing poisonous symptoms in very small doses while in other cases fairly large doses are tolerated. This is probably due to variations in its purity and mode of manufacture The hyoscine used in this case was Merck's. Professor J. Dixon Mann in his work on Toxicology states that in one instance $\frac{1}{40}$th of a grain taken by the mouth produced severe symptoms of poisoning, as did $\frac{1}{30}$th of a grain given hypodermically in another. On the other hand, Allan Gray[1] reports a case where $\frac{1}{10}$th of a grain was used every night with good effect. Dr. L. A. Weatherly, who used it largely in asylum practice, in an article in the *Journal of Mental Science* for July, 1891, states that he considers that the dose should be from $\frac{1}{200}$th to $\frac{1}{100}$th of a grain, very cautiously increased in some cases to $\frac{1}{50}$th. With regard to antidotes, besides those used in this case pilocarpine has frequently been employed. I had it with me but I did not use it and I confined myself to the use of strychnine, morphine, and caffeine, the last both hypodermically and as strong coffee, and it is in a great measure, I think, to the last drug that the patient owes his recovery.

Liverpool.

SUCCESSFUL REMOVAL OF A VAGINAL TUMOUR DURING PREGNANCY.

BY L. C. MARTIN, M R.C.S. ENG., L.R.C.P. LOND.

ON Oct. 13th, 1903, I was called to see a patient alleged to be in premature labour. The presence of some hæmorrhage rather than labour pains which, as a matter of fact, were absent, made her think that labour had begun. She stated that she was about seven months pregnant. On examination I found a tumour of about the size of an orange protruding just outside the vagina and having the appearance of a polypus On its lower and posterior aspect there was a slough about three-quarters of an inch in diameter; throughout the greater part of its extent it looked congested and felt somewhat hard. I had no difficulty in replacing it in the vagina, the manipulation, however, leading to some hæmorrhage. I then made a vaginal examination and ascertained that it was not connected in any way with the cervix or os uteri, both of which were perfectly free and normal, but that it was attached along the posterior wall of the vagina It extended upwards for a couple of inches by a broad and shallow attachment, there being no pedicle. I advised its removal as soon as possible, as I had no doubt that it would prove a [illegible] urely. In [illegible] its septic [illegible] ossibly be overlooked.

On Oct. 15th I operated under A C.E. mixture and removed the tumour. There was a considerable amount of hæmorrhage during the operation owing to the great vascularity of the tumour; one large vein in particular gave some trouble and had to be ligatured. The oozing after removal was also troublesome and yielded to packing of the vagina with double cyanide gauze soaked in lukewarm carbolic lotion of strength 1 in 50 The subsequent progress of the case was entirely satisfactory and calls for no remarks. On the eleventh day after operation the patient was up. She was confined on Dec 2nd, labour being quite normal and the child healthy and well developed. The patient's previous history contains nothing of importance. I had attended her two years previously when I had to deliver her with forceps owing to a face presentation.

The following is the report of the Clinical Research Association on the histology of the tumour: "There is no evidence of malignancy in this specimen. It consists of fibro-muscular tissue permeated with very large veins, many of which are thrombosed. The surface is ulcerated and inflamed. These appearances suggest that the tumour was primarily a varix of the vaginal wall which has become polypoid and inflamed."

I have considered this case worth recording for the following reasons: (1) because of the occurrence and removal of the tumour during pregnancy; (2) because of the fact that labour was not induced by the unavoidable and frequent manipulation which the operation and subsequent dressing involved; and (3) because of the rather unusual site of the tumour.

Woolston, Southampton.

CENTRAL MIDWIVES BOARD.—At the last meeting of the Central Midwives Board, upon consideration of applications for certificates the names of 270 women were passed under Section 2 of the Act and ordered for entry on the roll. Of this total 65 claimed as holding the certificate of the Obstetrical Society of London, five that of the Rotunda Hospital, Dublin, one that of the Coombe Lying-in Hospital, Dublin, one that of the Liverpool Lying in Hospital, eight that of St. Mary's Hospital, Manchester, two that of the Salvation Army Maternity Home, and 188 were admitted as having been in *bonâ-fide* practice for one year prior to July 31st, 1902.

ST. GEORGE'S HOSPITAL.

CONSERVATIVE OPERATION IN A CASE OF ACUTE SUPPURATIVE SALPINGITIS.

(Under the care of Mr. HERBERT W. ALLINGHAM.)

FOR the notes of the case we are indebted to Mr. T. Crisp English, surgical registrar.

The patient, a female, aged 17 years, was admitted into St. George's Hospital on Oct 20th, 1903. Five days previously she had been seized with abdominal pain referred at first to the umbilical region and later to the right iliac fossa Vomiting occurred at the onset of the pain and twice on the following day. The pain became more severe in spite of rest in bed; the bowels acted once during the week before admission, no purgatives or enemata being used. Micturition had been painful and the vaginal discharge, which had existed for several months, had become more profuse. There was no history of a similar attack previously and in other respects she had always been healthy; menstruation had been regular, the last flow occurring a [illegible] ourished. [illegible] and the tongue was dry and furred. Pain was complained of over the entire abdomen but mostly in the right iliac fossa and the knees were drawn up. The abdominal wall moved but slightly with respiration; there were great tenderness and rigidity in the lower part of the abdomen, most marked on the right side; no swelling could be felt and there was no distension or abnormal dulness. A diagnosis of appendicitis or mischief in the right side of the pelvis was made.

Operation was performed by Mr. Allingham about one hour after admission. The abdomen was opened by an oblique incision over the right iliac fossa but the appendix was found to be healthy; further examination showed that the trouble was in the pelvis. The incision was therefore prolonged downwards. The right Fallopian tube was swollen and injected; on pressure a quantity of pus oozed from its fimbriated extremity which was patent. A similar condition was found on the left side but a larger quantity of pus was present; the uterus and ovaries were normal. The case seemed particularly suitable for conservative treatment, as the pelvic peritoneum was only slightly involved and there was complete absence of adhesions. The pus was therefore thoroughly pressed out of the tubes, the surrounding parts were carefully cleansed with sponges and a large strip of iodoform gauze was passed from the lower angle of the wound into Douglas's pouch, and the upper part of the [illegible] in the ordinary way. No pain, vomiting, wor [illegible] tion. The bowels were or [illegible] a turpentine enema and ope [illegible] flatus passed freely through a rectal tube. The temperature became normal on the third day. The gauze plug was removed three days later and a tube was inserted in its place; this was finally removed on the twelfth day. During the third week the patient had a slight rise of temperature with pain in the left hypochondriac regions but no local signs either in the thorax or abdomen were found to account for this. The symptoms were relieved by antipyrin and bismuth. She got up at the end of the fourth week, the wound being soundly healed, and was sent to the convalescent home on the thirty fifth day after operation.

Remarks by MR. CRISP ENGLISH —Only within recent years have conservative operations upon the uterine appendages been advocated and carried into practice. The value of conservative treatment, however, is not yet generally recognised and many still consider that removal of the tube and ovary *en masse* is the necessary treatment for disease of either of these structures. One of the first principles of surgery is to remove as little as is consistent with the safety and welfare of the patient, yet in the majority of cases of suppurative salpingitis the ovaries are removed with the tube. It is probable, though not certain, that the ovaries produce an internal secretion of essential importance in the maintenance of health in women and this is the strongest reason for urging that they should be left unharmed whenever possible. In certain cases more than this may be done; diseased tubes may be treated locally and may be left in their normal position with a fair probability that they will remain functional.

The possibility of restoration of function in diseased tubes has been clearly proved by clinical experience. Some of the cases thus treated have subsequently required laparotomy for other conditions and the tubes have then been found to be free from adhesions and apparently normal; in other instances pregnancy has followed and thus demonstrated that one at least of the tubes has remained patent.

The objections raised against this treatment are mainly theoretical, for the published records of conservative operations show no increased mortality and it has yet to be proved that the risks of extra-uterine gestation are greater than in patients with normal Fallopian tubes. It is said that chronic pelvic pain as the result of adhesions is a contra-indication to conservatism, but it is doubtful whether these adhesions are greater with conservative than with radical treatment, and even should they give rise to some chronic pain the patient is in a much better condition than if she had had her appendages removed.

The chief arguments in favour of conservative treatment in the case published above were the following. 1. There was the age of the patient; a healthy patient of this age would normally have some 30 years during which menstruation and the possibility of pregnancy would continue. Complete oöphorectomy would have entailed the troubles associated with premature menopause, whilst removal of the tubes would have condemned the patient to certain sterility, and in the case of a young girl these matters are of the greatest consequence. 2. The local conditions were favourable for conservatism. The tubes were free from adhesions, their fimbriated extremities were open, and there was but little reaction in the pelvic peritoneum. If there had been much peritonitis with extensive adhesions the prospects of restoration of function would have been small. 3. The disease was apparently gonorrhœal in origin and the prognosis was thus far more favourable than in cases where the mischief is due to other pyogenic organisms.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

CASES IN WHICH DEATH OR COLLAPSE OCCURRED AFTER EXPLORATORY PUNCTURE OF THE CHEST.

(Under the care of Dr. THOMAS OLIVER.)

CASE 1.—The patient was a man, aged 62 years, who when admitted into the Royal Infirmary, Newcastle-upon-Tyne, was supposed to be suffering from an unresolved pneumonia, the sequel of an acute attack which had commenced five weeks previously, and possibly, too, from the presence of fluid in the pleural cavity. There was dulness at the lower part of the right lung posteriorly, reaching as high up as the inferior angle of the scapula. Although the breath sounds were feeble at the base still a few crepitant and submucous râles could be heard there. The heart sounds were weak and there was distinct epigastric pulsation. The expectoration was abundant; it was frothy, muco purulent in appearance, slightly blood-tinged, and extremely fœtid. No tubercle bacilli were found in the sputum. The temperature was never high. Albumin and sugar were absent from the urine. On the sixth day after admission the senior house physician of that date inserted a needle into the right chest, the patient meanwhile sitting upright in bed. As no fluid was found the needle was withdrawn and reinserted into another part of the chest wall, when almost immediately afterwards the patient fell back in bed dead. At the necropsy the left lung was found to be somewhat emphysematous; the right pleural cavity contained several ounces of pus; the right lung was consolidated at the base and contained two small abscesses.

CASE 2.—In another patient, a man about 36 years of age, exploratory puncture of the pleural cavity did not produce any inconvenience at the time beyond slightly increased rate of breathing, but it was followed a few hours afterwards by delirium. The man became light-headed and died on the following day, death being undoubtedly an indirect result of the puncture.

CASE 3.—In this case, that of a man who had physical signs of fluid in his chest, no fatal effect followed the puncture, but for a period afterwards he was extremely ill. Exploratory puncture of the pleura was in him attended by very marked cyanosis and by the expectoration of large quantities of a thin, foamy mucus. The lividity persisted. For several hours the patient was collapsed and extremely ill but in two days he rallied.

Remarks by Dr. OLIVER.—Since in a large number of cases exploration of the chest by acupuncture has come to be regarded as a necessity, either for the purpose of confirming a diagnosis or for arranging a line of treatment, and is usually a simple and safe operation, it is yet well to remember that now and again, and without any signs of warning, puncture of the pleural cavity may be followed by a fatal result either immediately or a few days after the operation. In the St. Thomas's Hospital Reports, vol. xxxviii., Dr. A. E. Russell draws attention to this subject and gives the details of three cases in which there quickly supervened upon exploration of the chest by the needle a series of alarming symptoms. In one instance, that of a girl eight years of age, there developed lividity, signs of cardiac failure, muscular rigidity, and double convergent squint followed by death. In another patient, a girl, seven years of age, the operation was succeeded by collapse and convulsions; while in a man, aged 52 years, there quickly developed, after exploration of the chest symptoms of cardiac failure, cessation of breathing, convulsions, and loss of consciousness that was never regained. Two of Dr. Russell's patients died within three days after the exploratory puncture—a result attributed to the surgical procedure.

My object in publishing the above cases is to bear witness to the fact of death having occurred in circumstances similar to those mentioned by Dr. Russell. I can recall at least four patients into whose chest the insertion of a needle, either for diagnostic purposes or for determining a particular line of treatment, was followed by fatal consequences.

What is the probable explanation of death occurring in the above-mentioned circumstances? Since in two of Dr. Russell's patients, and in one of my own, exploratory puncture was followed by symptoms suggesting cerebral vascular derangement it may at once be stated that at the necropsies upon the bodies at St. Thomas's Hospital no trace of embolism or of thrombosis was found. Dr. Russell is of the opinion that death was induced through reflex action. When death has followed exploratory puncture of the chest there has probably occurred cardiac and respiratory inhibition. It is more than likely that in some way or other the pulmonary branches of the vagus nerve are irritated and thus inhibition is reflexly induced. In a series of experiments carried out by Dr Russell and Dr. T. G. Brodie it was found, when the root of the lung in an animal was exposed, that if the pulmonary branches of the vagus were stimulated not only was the ventricular systole of the heart arrested but the breathing, ceased as well owing to inhibition of the respiratory centre. Since, too, there is a tendency for œdema of the lung to be rapidly developed, judging from the foamy and sometimes blood-stained expectoration that wells up into the mouth, it would appear as if the vaso-motor centre might become affected. It is also possible that as a consequence of the compression the vagal nerves have been subjected to, or as a result of some inflammatory change, the nerve fibres become unduly sensitive to irritation. Rapid expansion of a collapsed lung under forcible aspiration is a procedure not altogether devoid of danger. Dr. Russell suggests anæmia of the brain as an explanation of the cerebral symptoms. He attributes the anæmia to a sudden fall of the arterial pressure. Death is not, so far as one can tell, the reflex result of pain. Whether the anticipation of pain likely to be caused by the insertion of a needle into the chest may not in a highly sensitive patient favour the occurrence of syncope I am not prepared to say I have known sudden death occur when an empyema was being emptied, the patient all the time being under the influence of chloroform. Such a circumstance points to the improbability of pain *per se* as the cause of death.

The precautions to be observed are avoidance by the patient of the sitting posture in bed at the time of the exploratory puncture, the administration by the nurse of brandy shortly before the operation, and should the heart cease beating or the breathing become suspended during or after the puncture immediate resort by the medical attendant to artificial respiration and the injection hypodermically of ether and strychnine.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Art[illegible] of the Orbit.—"Silver Wire" [illegible]—Pemphigus of the Conjunc[illegible] [illegible] Opacities of the Cornea.— [illegible]

A CLINICAL evening of this society was held on Dec. 10th, 1903, Mr. JOHN TWEEDY, F.R.C.S., the President, being in the chair.

Mr. N. C. RIDLEY showed a case of Arterio venous Aneurysm of the Orbit, recurring six months after ligature of the common carotid. The condition was probably due to a traumatic communication between the cavernous sinus and the carotid artery.—Mr. E. L. PRITCHARD showed a case of the same nature with corresponding result, and experiences in connexion with such cases were narrated by Mr. JOHNSON TAYLOR, Mr. W. ADAMS FROST, Mr. G. HARTRIDGE, Mr. P. FLEMMING, Mr. E T. COLLINS, and Mr. E. NETTLESHIP.—Mr. E W. BREWERTON thought that owing to the free communication between the branches of the two external carotid arteries it would be much better to ligature the internal carotid artery.—Mr. J. H FISHER considered that the result of ligature of the internal carotid must be doubtful, as it probably depended upon the size of the communicating arteries in the circle of Willis far more than upon the communications of the branches of the external carotid. For this reason he thought it unlikely that ligature of the internal carotid would be better than ligature of the common carotid, to say nothing of the much greater difficulties of the operation.—Mr. RIDLEY, in reply, did not think that ligature of the internal carotid would be any more likely to cure the condition than the operation on the common carotid. If he did anything more to his patient he should feel inclined to clear out the orbit, but in this case, as apparently in most of the others mentioned, the patient had derived much relief, although the condition could not be said to be cured.

Mr. FLEMMING showed the drawing of a Fundus with Marked Arterial Degeneration. The patient was a woman, aged 48 years, with granular kidney. She died from apoplexy a few weeks after the drawing was made. During life the arteries had a typical sclerosed appearance with "silver wire" lines along them. There was venous obstruction at the points where they crossed the veins. There were also hæmorrhages in the retina. Microscopic sections were shown of the retina with photomicrographs; there was enormous thickening of the vessels.—Mr. R MARCUS GUNN showed specimens of "silver wire" arteries from a similar case.—Mr. R W. DOYNE showed a woman, aged 54 years, with somewhat similar ophthalmoscopic appearances. Her urine was healthy but the radial arteries were thickened.—A discussion followed on the cause of the apparent constriction of the veins by the arteries.

Mr. DOYNE also showed a case of Retinal Effusion in a patient, aged 65 years, whose sight had recently failed There was no history of syphilis but years ago he had had gonorrhœa

Mr. WILLIAM ANDERSON showed a case of Conjunctival Pemphigus.

Mr. W. T. HOLMES SPICER showed a case of Hereditary Nodular Opacities of the Cornea and some drawings. It was, he said, a family disease, though probably not congenital. Fuchs in one case had removed a portion of the cornea and found it softened and Bowman's membrane absent. The deposit, which was amorphous, lay in the substantia propria. One observer had described the deposit as urate of soda but Mr. Spicer doubted whether it were so. The condition was progressive and in Mr. Spicer's example the father and a daughter were affected.—Mr. JOHNSON TAYLOR described a somewhat similar condition that he had seen in puppies; it [illegible]

Unilateral Anophthalmos. The child was very feeble and delicate and without an anæsthetic it was impossible to say if a rudimentary eye existed.—Mr. TWEEDY commented on the term used in describing this case. He thought that the condition should be termed "anophthalmia" and the child described as "anophthalmos."

CLINICAL SOCIETY OF MANCHESTER.

The Treatment of Severe Cases of Accidental Hæmorrhage.

THE monthly meeting of this society was held at the Palatine Hotel on Dec. 15th, 1903, Dr. W. MILLIGAN, the President, being in the chair. There was a large attendance.

Dr. H. BRIGGS (Liverpool) opened a discussion on the Treatment of Severe Cases of Accidental Hæmorrhage. He said he believed that there was a *primâ facie* case for reconsideration. He alluded to the original cases of Rigby, published in the sixth edition of the essay on "Uterine Hæmorrhage which Precedes the Delivery of the Full-grown Fœtus" Of the 42 cases of placenta prævia treated by Rigby by turning 31 women recovered and 11 died. Dr. Briggs also alluded to the disproportion of 42 cases of placenta prævia to 64 of accidental hæmorrhage, probably showing that the 64 cases of accidental hæmorrhage included many instances of lateral placenta prævia, *Rigby having apparently confined his cases of placenta* prævia to those in which the placenta was either over or on the internal opening of the cervix. Allowing for the cases of lateral placenta [illegible] Rigby as cases of acc[illegible] many severe ca[illegible] own words: "Many were alarming cases, as the patients had lost large quantities of blood and were extremely faint; not one proved fatal. They all terminated safely by waiting for the efforts of nature to expel the contents of the womb." Rigby had keenly appreciated the sources of danger in the treatment of cases of placenta prævia by podalic version. He avoided the greater risk of to[illegible] cervix and accepted the lesser or[illegible] relaxation by pains and discharg[illegible] The treatment he advocated differ[illegible] Cases of accidental hæmorrhage [illegible] placenta prævia) Rigby treated by palliation and waiting for nature's efforts to complete delivery, and cases of placenta prævia (central, partial, marginal, and some lateral) by more prompt delivery by art by turning. Dr. Briggs went on to say that Rigby did not as a routine practice rupture the membranes and he always before doing so waited for the pains of labour. Dr. Briggs considered that the prominence accorded to Rigby's observations and conclusions in this country was justified by a study of earlier, contemporary, and later work. Dr. Briggs then reviewed the earlier history of the subject, illustrated the improvement in the results of the treatment of cases of placenta prævia achieved by the adoption of gentler and more precise methods of controlling the bleeding, and asked whether corresponding improvements in the results of the treatmen[illegible] shown.

Rotunda [illegible] paper on the Treatment of Accidental Hæmorrhage published in the *Journal of Obstetrics and Gynæcology of the British Empire* in August, 1902. He considered that the Rotunda Hospital method (the application of pressure by an abdominal binder, vaginal tampon, and perineal bandage) seemed to have been effective in controlling the hæmorrhage in the most difficult class of cases to treat, in which, with accidental hæmorrhage, the os uteri was closed and there were no pains of labour. The patient suffered from shock but possessed a chance of recovery. He considered that the maternal mortality in this alarming complication had been reduced to a more encouraging level by the Dublin method. In conclusion, he quoted cases from his own practice.

Dr. W. K WALLS remarked that some five years ago he had summarised his observations on 38 severe cases in a contribution to the North of England Obstetrical Society. He considered the term "accidental hæmorrhage" a misnomer and in some measure responsible for unsatisfactory treatment. He believed that the cases should be regarded as influenced by some toxæmia of pregnancy and instead of "accidental" would prefer to speak of "avoidable" or toxæmic hæmorrhage, for the patients almost invariably expressed themselves as "never having been well during pregnancy" and in the majority of very severe cases the urine was loaded with albumin. When face to face with the grave emergency of a very severe case Dr. Walls mentioned the three great indications which guided his practice: first, to improve the patient's condition by quiet, rest, food, stimulants, and warmth, and encouraging the uterus to overcome its inertia by friction, binder, and vaginal plug, or de Ribes's bag. In the absence of proper uterine action, as shown by the cervix undergoing dilatation, Dr. Walls strongly condemned the practice of rupturing the membranes. The second indication was to deliver the patient if improvement ceased to follow the preliminary treatment (and this indication might include an *accouchement forcé*. Thirdly, it was necessary to guard especially against post-partum inertia and hæmorrhage.

Dr. W. J. SINCLAIR said that in his opinion true cases of accidental hæmorrhage were extremely rare, not more than 1 in 10,000, but when they did occur energetic treatment was demanded.

Dr. T. A. HELME agreed with Dr. Sinclair that interference by art was necessary, so that if there was a fatal result they could not reproach themselves that the patient had died before their eyes without anything having been attempted.

Dr. W. E. FOTHERGILL explained the rationale of the Dublin treatment of accidental hæmorrhage. A healthy uterus could not be distended to more than a certain extent, therefore if escape of blood from the cervix could be prevented by vaginal plugging the tension within the uterus would soon equal the blood pressure and bleeding should cease. In a diseased uterus, however, distension could go much further than in a healthy one and thus in cases of concealed hæmorrhage most of the blood in the body might escape into the uterus. An advantage of abdominal section in these cases was that if uterine inertia from local disease or any other cause should persist after delivery of the fœtus the uterus itself could be removed, a course which would give the patient the best chance in very serious cases.

Dr. P. R. COOPER thought that cases of severe accidental hæmorrhage were not very rare. The chief guide to correct treatment should be the condition of the uterine muscle. Where this was active or responded to stimulation, expediting delivery by the ordinary methods, or even by Bozzi's dilator, would probably suffice. Where, however, the uterus was completely inactive and irresponsive, forcible extraction was absolutely contra-indicated. A Porro's operation would probably give the patient the best, if not the only, chance of recovery. Regarding the after-treatment of the hæmorrhage and shock adrenalin was suggested as likely to prove useful for both indications.

Mr. E. STANMORE BISHOP urged definition of the object of the discussion and the more scientific consideration of the anatomy of the vessels supplying the blood lost. He pointed to the advantages of compression of the aorta to control the arterial supply and the elevation of the lower half of the body and legs to affect the venous supply. The essential thing was to keep the respiratory and cardiac centres supplied and so to obviate the tendency to death.

Dr. W. Y. MARTIN remarked that nothing had been said about ergot or ergotin and their preparations.

Dr. P. TYTLER suggested that in extreme cases as a last resource a clamp might be applied to the broad ligament so as to cut off the arterial supply of the uterus, but he did not know whether this had been tried.

Dr. BRIGGS replied and thanked the society for the interesting discussion on the views enunciated in his paper.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Dec. 16th, 1903, Professor JOHN CHIENE, the President, being in the chair.

Mr. C. W. CATHCART exhibited a female patient after Removal of a Calculus from the Common Bile Duct. For about 25 years she had suffered from various forms of gastric disturbance but whether these were associated with the calculus was unknown. For about a year, however, she had complained of severe dyspepsia with paroxysms like those due to gall-stone. As she was stout a long linear incision had to be made and a large stone was found impacted in the common duct. It could not be forced onwards so it was removed through the duodenum. The latter with the head of the pancreas was lifted forwards by Kocher's method of freeing the peritoneum, and the intestine having been opened on the free aspect the stone was removed. The patient has made an excellent recovery and can now eat anything, whereas formerly she could not take animal food.

Mr. J. M. COTTERILL showed the four following cases:—1. A man, aged 29 years, with Recurrent Sarcoma of the Shoulder manifesting marked improvement under treatment by the x rays. In January, 1903, Mr. Cotterill had removed a small sarcoma from the left shoulder of this patient. He returned to the infirmary, however, in October with a great recurrence of the disease. The man was exhibited at the meeting of the society on Nov. 4th when there were large ulcerating areas on the dorsum of the left shoulder as well as a marked growth in front. He had had 38 exposures of four minutes each to the x rays, or almost daily treatment, and whereas on Nov. 4th the lump was of the size of the fist, bleeding and fungating, it had now shrunk to a very small brawny infiltration. On commencing this treatment the pain disappeared at once and the bleeding within a few days. He had also increased six and a half pounds in weight. The growth was previously inoperable on account of its adhesions to the structures at the root of the neck but now it might be removeable. 2 A boy after Enterectomy for Tuberculous Stricture. He had for six months been ill with intermittent paroxysms of pain in the abdomen occurring every ten days, though between the attacks he was perfectly healthy and ate anything. The case was diagnosed as one of tuberculous peritonitis. On opening the abdomen a stricture of the intestine was discovered in a tangled mass of tuberculous tissue. The stricture was removed and the lumen was found to be so contracted that it only admitted a No. 6 catheter and yet had allowed the free passage of food between the paroxysms. 3. A man after Laminectomy for Paralysis of two years' standing. The patient, who was aged 36 years, had had complete sensory and motor paralysis of the legs, the anæsthesia extending as far upwards as the level of the anterior superior spines. Heat and cold sensory impressions were absent. The urine had a specific gravity of 1003 and was alkaline. On examination a projection of the ninth dorsal vertebra was found. At the operation the laminæ of the eighth, ninth, and tenth dorsal vertebræ were removed and a tuberculous lesion was found which had led to a bony deposit so constricting the cord that at one point the lumen was only of the size of a No. 12 catheter. In four months after the operation the patient went home much improved and at the end of the year he could walk almost perfectly. His urine was normal and could now be retained for several hours. His present occupation entailed his standing or walking almost the whole day. 4. A woman, aged 35 years, with a Tumour of the Frontal Bone. Mr. Cotterill was not prepared with a diagnosis; its slow growth was against its being a sarcoma.

Dr. A. LOGAN TURNER exhibited a girl, aged 12 years, after operation for Extensive Osteo-myelitis of the Temporal Bone, but not involving the middle ear. She had never had middle-ear disease and the membrane was intact and hearing was normal. A gradually increasing swelling formed behind the right ear, the bone felt distended, and the skin became discoloured. There was no rise in temperature until the evening preceding the operation. On incising the skin extensive mastoid disease was found extending to the lower part of the squamous portion of the temporal bone as well as to the occipital bone, the osseous tissue being full of pus and granulations. A large amount of bone was removed and the antrum was opened into. No evidence of tubercle was obtained but on examination of the sputum pneumococci were found.

Dr. TURNER also exhibited a girl, aged 10 years, after operation for Mastoid Abscess and Phlebitis of the Lateral Sinus with Ligation of the Internal Jugular Vein. At the operation the internal jugular vein was found to be thrombosed so it was ligatured and a large part was removed. Later the clot in the lateral sinus sloughed out. The child was making a good recovery.

Dr. H ALEXIS THOMSON exhibited (1) a female patient after Partial Gastrectomy for Cancer; and (2) a lad, aged 18 years, after operation for Perforated Gastric Ulcer. This latter was the youngest male patient whom Dr. Thomson had met with presenting this affection. For three weeks previously to the perforation he had suffered from gastric pain and vomiting.

Mr. F. M. CAIRD sent the following four cases:—1. A female patient after removal of a Malignant Stricture of the Pylorus and Malignant Stricture of the Jejunum. This double development of carcinoma was a very rare condition. As the diseased areas were widely apart, after the excision of the pyloric tumour a gastro-enterostomy was performed and then the tumour of the jejunum was removed. 2. A patient after operation for Hour-glass Contraction of the Stomach. 3. Two patients after Gastro-jejunostomy for Hæmorrhage. Both were cases of gastric ulcer and the object was to drain the stomach while giving no treatment to the ulcer itself. Both operations were successful in stopping the hæmorrhage. 4 A boy with Coxa Vara which looked like a case of congenital dislocation of the hip-joints, there being marked lordosis and projection of the great trochanters.

Dr. GEORGE A. GIBSON exhibited a boy with Peripheral Neuritis produced by arsenic. He suffered from chorea and was treated with 15 minims of liquor arsenicalis thrice daily for three weeks. The neuritis affected both feet, the left being the worst. The knee-jerks were absent and the muscles were atrophied. The condition was improving under massage.

Dr. ALEXANDER BRUCE sent (1) a woman, aged 35 years, suffering from Paralysis Agitans; and (2) a very unusual case of Post hemiplegic Tremor. The second of these patients, a female, had an attack of hemiplegia 18 months ago but recovered and six months later these curious movements commenced. The tremor consisted of very rapid flexion and extension movements of the fingers and thumb as well as of the wrist and at first amounted to 130 per minute. The movements were quite unlike the usual slow athetoid tremor subsequent to hemiplegia. On excitement they were greatly exaggerated and ceased during sleep, though this might be due to the fact that she slept on the affected arm so as to keep it quiet. Under the action of bromides and valerian there was a distinct improvement.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 15th, 1903, Dr. H. Angus, the President, being in the chair.—Dr. T. Jason Wood read notes on a case of Hydatid Cyst simulating enlarged prostate and causing complete retention of urine. The patient was a man, aged 68 years, who suffered from complete inability to void his urine. It was impossible to obtain any history as he was almost completely deaf and was of deficient intelligence. His friends knew nothing of what he had been doing for some time past. The bladder was distended up to the umbilicus and was relieved by a soft catheter which at first passed easily but after a few days only a silver instrument could be used successfully. Examination per rectum showed a large firm swelling in front of the rectum; it was smooth and rounded and no nodules were felt on it. A diagnosis of hypertrophied prostate (? tumour) was made. The patient was a healthy-looking man and showed no physical signs of disease. The urine was clear, acid, had a specific gravity of 1010, and contained no albumin at first. On the day of the operation, however, a trace of albumin was found. On August 6th suprapubic cystotomy was performed. On opening the bladder the swelling was at once seen, covered by the mucous membrane of the bladder. The urethral opening was in front of the swelling and hidden by its projection into the bladder cavity. On incising the bladder mucous membrane it was found to strip readily from the swelling and the latter was seen to be covered by a dense parchment-like membrane. It was not found practicable to enucleate the tumour owing to the limitations of the wound in the bladder and the depth to which it extended. The covering of the tumour was then incised and the nature of the case made evident by the escape of a large quantity of hydatid daughter cysts As much as possible of the cyst wall was cut away from the front and the cavity was packed with gauze, the end of which was brought out through a wound into the cyst through the perineum. The peritoneal cavity was accidentally opened during the attempt at enucleation of the cyst. The bladder wall was sewn up with interrupted catgut sutures, the suprapubic wound was partly closed, and a large drain was inserted. The patient did well for 12 days after the operation except that he was troubled with hiccough; this, however, ceased on the sixth day after the bowels had been well moved. There was no escape of urine through the perineal wound, there were no signs of peritonitis, and both wounds looked healthy. The temperature was normal but the pulse was quick (110 per minute). He took nourishment well. On the thirteenth day he became lethargic and refused his food, coma gradually supervened, and he died on the fifteenth day after the operation, apparently from uræmia. Post-mortem examination showed the cyst in the recto-vesical space; the peritoneal cavity was shut off by adhesions and the bladder wound was healed by soft tissue. The kidneys were cystic and their total weight was eight ounces. The ureters were dilated. There were numerous small cysts in the liver with no sign of hydatid disease elsewhere. The prostate was natural in appearance and size and in close relation to the cyst wall. The other organs were fairly healthy.—Mr. F. Farrow, Dr. B. H. Slater, Dr. David Goyder, Dr. J. B Hall, and the President made remarks on the case —Dr Goyder made remarks on a case in which there were Peculiar Phenomena attending Menstruation.—Dr. F. W. Eurich read notes on a series of cases of Epilepsy in which "fits" were not the prominent symptom. In some of them there were acute maniacal attacks with homicidal tendencies. In one case lapses of consciousness occurred in which the patient wandered away and did not remember where he had been.—Microscopical and pathological specimens were shown by Dr. Eurich, Dr. Slater, and Dr. O. M. F. Althorp.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held on Dec. 10th, 1903, to hear a paper by Dr. W. D'Oyley Grange of Harrogate on Normal Saline Baths. Dr. Thomas Richmond, the President, occupied the chair.—Referring in the first place to the presence of sodium chloride in the tissues and fluids of the body, Dr. Grange proceeded to speak of the preservative properties of saline solution on dead tissues as compared with the action exercised by plain water. The outlines of treatment of rheumatic conditions at Harrogate were sketched and the speaker went into considerable detail as to the action of saline solution as compared with plain water in various forms of disease. The power of saline fluid as a stimulant and reviver in a depleted body, when injected by a vein or into the tissues, was briefly referred to, and this power Dr. Grange attributed to the readiness of absorption of the saline solution; plain water was not so readily absorbed by the tissues as plain water was not a normal constituent of these tissues. In dermatology saline fluid was of prime importance. The action of hot sea water and mineral water baths on the skin was explained by the existence of the non-irritating and even soothing effects of normal saline fluids. The difference in the ability for being absorbed was very marked between plain water and normal saline solution, so much so that whereas plain water might act as an aperient when taken by the mouth, normal saline solution had the reverse effect, its readiness of absorption having a very marked action on the kidneys. It was for this reason that he advocated the use of plain water at night and saline solution in the morning. Describing the waters of Harrogate Dr. Grange mentioned that the two principal ingredients of these waters were sodium chloride and sulphur which, next to sodium chloride, was most necessary to the metabolism of the body. Harrogate water or normal saline solution taken in the morning prevented uricæmia. Dr. Grange finally enumerated a number of conditions which called for the exhibition of normal saline solution; it was used for flushing the peritoneal cavity in cases of septic peritonitis; it was also useful in the washing of wounds; it was called for when washing was required or desired in irritable conditions of the skin; and its exclusive use was regarded almost as a specific in "chapped" hands. While speaking of rheumatism, especially of the low, subacute, or chronic variety, Dr. Grange emphasised the necessity of inquiring very carefully after any possible septic focus which might render the case intractable to treatment, and otorrhœa, rhinitis, balanitis, gonorrhœa, leucorrhœa, and anal fissure were instanced as having an etiological interest in this connexion. In cases where such might not be discoverable the drainage was advised to be investigated. In rheumatism in women, too, the condition of the generative system, and especially the pelvic organs, ought to be carefully reviewed.—The subject was very fully discussed by the members and some interesting points in the septic theory of the causation of rheumatism were brought out.—A cordial vote of thanks, on the proposal of the President, seconded by Dr. Renton, was accorded to Dr. Grange.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The third meeting of the session of this society was held at the Guildhall, Windsor, on Dec. 16th, 1903, Mr. W. B. Holderness, the President, being in the chair.—Dr. E. B. Hulbert read a paper entitled "The Importance of an Adequate Fluid Intake in Various Morbid Conditions." He said that the normal quantity of water that should be taken to compensate the daily loss should not fall below 40 or 50 ounces and mentioned among the various morbid conditions due to deficiency of liquid intake gout and its different manifestations. Migraine often connected with gout was, he said, much benefited by increasing the amount of liquid consumed. The relation of temporary increase of intraocular tension to migraine was alluded to and attention was drawn to the good results obtained by increasing the fluid intake in this condition and also in progressive myopia. The value of increasing the aqueous intake in anæmia was also mentioned and stress was laid on the importance of adding plenty of water to each dose of iron. Dysmenorrhœa was also specified, as also was the collapse following severe gastro-enteritis and hæmorrhage. Finally, Dr. Hulbert alluded to a case of bilateral parotitis in an aged patient which had apparently yielded to this line of treatment.—Dr. Alexander Haig, while agreeing with Dr. Hulbert that in gout and similar conditions where poisons were circulating in the blood free dilution of the blood would be likely to benefit the patient, said that it was difficult to explain that in migraine where the blood pressure was high good results should follow the ingestion of fluids—a proceeding which tended to raise the blood pressure. The same difficulty presented itself in other diseases mentioned by Dr. Hulbert, anæmia and dysmenorrhœa, where in practice Dr. Haig's conclusions did not tally.—Dr. Rayner D. Batten said that though he had no experience of gauging the blood pressure by the instrument employed by Dr. Haig his finger told him that copious draughts of water tended to lower the blood pressure, and he thought that this was the common experience. In treating acute glaucoma he thought that the time allowed was too short for treatment on general lines to do good. Besides, glaucoma having a more or less mechanical origin, treatment by operation seemed to be the most reasonable plan. He thought, however, that Dr. Hulbert's line of treatment might prove useful as a preventive measure. With regard to progressive myopia he said that the question as to why the sclerotic yields in this disease was still unanswered. In prescribing spectacles one was only treating the symptom of a disease, and he thought that it was quite possible that subsequent experience would prove that it was a cardiovascular change. He concluded by expressing the hope that more work would be done in this direction and his belief that such work would tend to show that Dr. Hulbert's advice as to the treatment of progressive myopia was based upon sound principles.

FORFARSHIRE MEDICAL ASSOCIATION.—The third ordinary meeting of this society was held in the University College, Dundee, on Dec. 11th, 1903, Dr. W. Graham Campbell, Vice-President, being in the chair.—Patients and specimens were shown by Dr. J. S. Y. Rogers, Dr. J. Mackie Whyte, and Dr. W. E. Foggie.—Dr. R Stirling of Perth gave an account of a case of Gastric Ulcer with Perforation which he had treated by suturing. The convalescence was delayed by diaphragmatic pleurisy following operation. He had kept up rectal feeding for a week after the operation —Professor David MacEwan referred to the difficulty in the diagnosis of such cases. In most suspected cases he thought that it was safer to operate — Dr. Mackie Whyte mentioned a case of recovery after symptoms all of which pointed to perforation. He discussed the advisability of giving morphine in small doses so as not to mask the symptoms.—Dr Stirling replied that in his case there were almost no symptoms of previous gastric mischief.—Dr. C. Templeman introduced the subject of the Municipal Supply of Sterilised Prepared Milk. He emphasised its importance and pointed out the success which its adoption in Liverpool, Battersea, and Leith had met with. He mentioned it as one possible preventive of the growing infantile mortality in Scotland and especially in Dundee. One thing, however, that must be guarded against was the inducement to mothers to shirk the proper nursing of their children. He considered that for the ultimate success of the proposed scheme the support of the medical profession of the city was necessary.—Professor A. M. Stalker thought it would be well not to cherish too high hopes of the success of the system to begin with. The people must have natural intelligence and natural affection, while a great deal depended on what happened after the baskets of nine bottles were handed over to the mothers. The system was a means of bringing before the working class the extreme importance of infant feeding, in which direction an immense amount of good could be done by the municipality. He considered it a good scheme and one which in the long run would be sure to impress itself on the populace.—Dr. A. P. Low dwelt on the necessity of proper veterinary inspection of dairies and spoke of the impossibility of cleaning the long glass tubes in some feeding bottles.—Dr. R C. Buist proposed a motion pledging the meeting to support Dr. Templeman and approving of his scheme.—Dr. Mackie Whyte, in seconding, said he thought that medical men should disabuse their minds of the idea that sterilised milk in infant feeding caused infantile scurvy and quoted Sir Thomas Barlow in support. Infantile scurvy had been caused by too long feeding on malted foods.—This motion was adopted unanimously.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Dec. 16th, 1903, Dr. J. Nigel Stark, the President, being in the chair.—Specimens were shown by Dr. Carstairs C. Douglas, Dr. R. Jardine, Dr. J. K. Kelly, Dr. G. Balfour Marshall, Dr. A McLennan, Dr. A. Louise McIlroy, Dr. Russel (for Dr. J. Edgar), and Dr. Taylor.—Dr. G. Scott MacGregor read a paper on the Management of Anterior and Posterior Displacements of the Uterus. The paper was discussed by Dr. Kelly, Dr. McLennan, Dr. Marshall, and Dr. Russel.—Dr. McLennan read notes of a case of Sarcoma of the Uterus. Hysterectomy was performed. The uterus was much enlarged. When split open it was found to contain a tumour involving the whole posterior wall and almost rupturing into Douglas's pouch. Dr. McLennan attributed the enlargement of the uterus to the poison secreted by the tumour acting on the myometrium.—Dr. J. Lindsay showed a Double Monster (Thoracopagus) and read a clinical note by Dr. Edgar. All the serous cavities in the two fœtuses were separate except the pericardium which was single and contained the hearts. The organs were normal except that the liver was composite. Dr. Lindsay gave a description of the circulatory arrangements.

Reviews and Notices of Books.

Sir Henry Wentworth Acland, Bart., K.C.B., F.R.S., Regius Professor of Medicine in the University of Oxford: a Memoir. By J. B ATLAY, late Scholar of Oriel College, author of "Lord Cochrane's Trial before Lord Ellenborough." London: Smith, Elder, and Co. 1903. Pp. 507. Price 14*s.* net.

IT is rather to be feared that this book may fall chiefly into the wrong hands: that it will not be seen by many who would be greatly interested in the record of a full, active, and useful life; and that, on the other hand, it will be read or at least looked into by many who have been taught to regard Sir Henry Acland as a great physician and who may therefore be disappointed in the record given. As a physician he was rather good than great and the course of events took him far afield from the quiet routine which is almost essential to the successful work of a leader of medical science.

To understand thoroughly the essential characteristics of Sir Henry Acland it is necessary to appreciate his hereditary disposition and his upbringing and it may be best to say first a few words on these points, for if they are not kept in mind a reader who had never met him in life and who for the first time makes his acquaintance through this book may be inclined to form an opinion of him which is not justifiable and to conclude that his undoubted success was due rather to luck than to the solid and great qualities which he undoubtedly possessed.

There is a saying in Devonshire—and as it is quoted in the book, we can refer to it without apology—that "the world is made up of men, women, and Aclands." Like most sayings which live it is not without meaning. Acland appears always to have judged things and people from his own particular standpoint. Fresh from Harrow, Oxford, and the plains of Troy, he was ready to write in the manner of an old stager on life in London, as learnt from a study of the medical students at St. George's Hospital. He resembled in some respects the amiable Mr. Barlow and had he been wrecked on a desert island it would probably not have seemed incongruous to him to adopt on Sundays the chimney-pot hat, without which, it may be remembered, Mr. Seagrave never walked abroad. A disquisition on the advantage of savings banks which Acland gave to some naval boys after presenting them with a shilling each did not apparently convert them to his views on these estimable institutions and he expressed himself as being shocked that so large a sum as the one which he had given to each of them should be expended in the acquisition of nuts and oranges—a course which he suggested might have been adopted by monkeys. Acland indeed took himself very seriously and resented it when he was not so taken by others. On a yachting cruise he drew up a series of rules and recommendations which were printed and hung up on deck for the instruction of the crew and of his guests. Amongst the rules was one "to obtain information as to sanitary wants of fishing villages and fishing populations whenever possible." On one occasion the exhilaration of a wet day ashore tempted some of his guests to write a somewhat playful report on the sanitary state of a fishing village. It was "received with eloquent silence and never referred to again."

A sense of humour is not a universal gift and if the general reader will pardon Acland for the deficiency he may find very much of interest in the book, for it shows clearly enough how great was the work he accomplished, how loveable he was as a man, how attractive to his friends, and how good to the poor. His life at Harrow was not happy but at Oxford he met John Ruskin who became his life-long friend. In the year of the accession of Queen Victoria—a period which seems very remote—he started for a tour to the East, visited Athens, Rome, and Constantinople and made drawings of the seven churches of Asia. Whilst a student at St. George's he preferred to the society of his fellow students that of Mr. George Richmond, the painter of Ruskin, of Newton of the British Museum, and of Philpott, then a master at Charterhouse, afterwards Canon of Hereford. At this period Richmond made a very fine drawing of him, which is reproduced in the book. It is curious that Ruskin either disliked it or thought it not good.

Acland soon left London and studied in Edinburgh. His health was delicate and Brodie warned him that if he settled in London he would not live till he was 40 years of age, and added that the "well-informed and intellectual society of Oxford" would be good for him. He was appointed to Lee's Readership and he married Sarah Cotton. His marriage proved the greatest blessing and gave him a fixity of purpose which he might never otherwise have obtained. Mrs. Acland became an ideal housewife and mother, was the kindest and most considerate of hostesses, and exercised the strongest power for good on what may be called the domestic university life of Oxford. Acland from time to time entertained successively and pleasingly a number of strange guests, a thing impossible in the absence of a hostess endued with kindness, with tact, and with common sense. Of the work done by Acland during the cholera epidemic of 1854 nothing need here be said and the great fight of his life—that for the establishment of the science museum at Oxford—is too well known to be here repeated. In 1857 he was appointed Regius Professor of Medicine and it is in that position that he was best known to the world at large. In 1858 he travelled with the King (then Prince of Wales) to Canada and his visit to America proved a great success and increased the number of his friends. Acland regretted the position taken up by Samuel Wilberforce in regard to science and saw clearly that it was untenable; he equally regretted the action of Owen in regard to Huxley. The book contains a very characteristic letter by Tyndall in which he says that, in his opinion, the English clergy appear to him "to be specially endowed with the capacity of bringing into contempt the noblest aspirations of the human mind."

Acland was a great hater of injustice and was profoundly disgusted with the treatment meted out to Sir Bartle Frere who was in turn disgracefully ill-used by Lord Beaconsfield and by Mr. Gladstone. A thoroughly religious man he saw the weakness of the position taken by Gladstone on "The Impregnable Rock of Holy Scripture"; his own teaching—which had the entire approbation of Henry, Cardinal Newman—is concisely expressed in one sentence of his Harveian Oration. "No student of Nature worthy of the name looks on the problem of this world as other than vast and inexplicable. He pretends no more than to see by an image darkly and to bend before the cause of all which is by us unattainable, by us only comprehensible."

No one interested in the religious and scientific life of the middle of the last century can afford to ignore this book. Everyone familiar with the chief personalities of the last half of the century will read much of it with interest. Mr. Atlay must be congratulated on having carried out conscientiously and well a work which must have cost him time and no little anxiety, for to write a fair, critical, and true biography is a literary achievement of no small merit.

The Practical Study of Malaria and other Blood Parasites. By J. W. W. STEPHENS, M.D. Cantab., D.P.H., Walter Myers Lecturer in Tropical Medicine, University of Liverpool; and S. R. CHRISTOPHERS, M.B. Vict., I.M.S.; Members of the Royal Society's Commission on Malaria in Africa and India, 1898–1902. London: Longmans, Green, and Co. 1903. Pp. 378 xxxv. Price 10s. net.

IN recent years the subject of tropical medicine has been enriched by many notable works. The student of to-day has the great advantage of Dr. Scheube's encyclopædic treatise on tropical medicine, of Sir Patrick Manson's book, of Dr. Daniels's recently published "Laboratory Studies in Tropical Medicine," and lastly of the work now under review. The major portion of this publication is occupied with the subject of malaria and contains some very useful details in connexion therewith. The last chapters tell us of blackwater fever and the facts concerning the hæmamœbidæ, Texas fever, African coast fever, spotted fever, spirillar fever, trypanosomata, and the filaria.

In considering the subject of malaria the authors give us an account of the best and most simple technique according to their knowledge gathered from the extensive experience of several years and their labours on the Royal Society's Commission on Malaria. They have found that for ordinary work it is better to use almost entirely dry films and the book opens with a description of the technique by which the latter are prepared. The making of wet films is also described. In the staining of films preference is, we think, rightly, given to Romanowsky's method which is fully described. Leishman's stain is also dealt with, and this is, perhaps, easier to carry out. The description of normal blood next follows and is succeeded by an account of the abnormal constituents of the same. In the third chapter the important subject of the malaria parasite is treated very fully. Then we come to certain subsidiary signs of the affection and the differential count of the leucocytes. The description of the examination for the presence of the parasites in the tissues follows. The Cambridge rocking microtome in its ordinary form suffices for all practical purposes. The student is then taught how to imbed, the precautions in the matter of imbedding are detailed, hints on the cutting of sections are given, and this part of the subject terminates with directions concerning the staining and mounting of the sections. Altogether this chapter is an excellent one. We next find a sufficient account of the life-history of the malarial parasite. The description of the mosquito follows. The ovum, the larva of the mosquito together with other larvæ, the nymphæ, and their examination are next portrayed, and then follows a very useful chapter on the capture and experimental feeding of mosquitoes. The methods of the dissection and examination of mosquitoes for the malarial parasite are given very fully, the chapter containing this account being one of the most valuable in the work. After describing the internal anatomy of mosquitoes the authors next tell us how to collect mosquitoes, how to kill them, and how to mount them. Theobald's classification is mentioned. The more common situations in which the anopheletes breeds are collected together in a very useful table. Those whose duty it may be to investigate the endemic malaria of any place will find in the chapter relating to this part of the subject the fullest directions. The estimation of the red cells, of the leucocyte count, and of the hæmoglobin and the blood platelets is next considered. We note the authors' opinion that there is practically no difference between quinine hæmoglobinuria and blackwater fever; this, however, will not be admitted by a great many observers. It is stated by Dr. Stephens and Dr. Christophers that blackwater fever occurs only in those who have previously suffered from malaria. If this theory really be true it is at least remarkable that we have never seen blackwater fever in India, although many hundreds of cases of malarial fever treated by quinine have passed through our hands. The organisms of Texas fever, African coast fever, spotted fever, yellow fever, and spirillar fever receive due attention. The last two chapters deal with the trypanosomata and the filaria and the work closes with a very useful appendix on the blood-sucking flies and a description of the various stains, mounting media, and the apparatus required for work in the tropics. We have thus briefly reviewed the scope of this interesting work which, supplementing the excellent treatise of Dr. Daniels, will be found of great value to observers in the tropics.

Hypnotism, its History, Practice, and Theory. By J. MILNE BRAMWELL, M.B., C.M. Edin., author of numerous articles on the Practice and Theory of Hypnotism. London: Grant Richards. 1903. Pp. 477. Price 18*s.* net.

"The author" of this book, we are told by the publisher, "has devoted the last 12 years to hypnotic practice and research and his personal observations of the practical work done in France, Germany, Sweden, Holland, Switzerland, and Belgium should also make the volume a valuable addition to the science of a subject which is exciting much interest at the present time." In the introductory chapter the author tells us that in the course of the volume he proposes "to refer not only to his own hypnotic 12 years' practice and research but also to give such a general account of the subject as can be brought within reasonable compass." Examining Dr. Bramwell's book in the light of his own account of his intentions we doubt if he has fulfilled the promises made. One chapter is devoted to the early history of hypnotism; it is short and very incomplete; for example, the account given of Mesmer is fragmentary. The work of Elliotson, of Esdaile, and of Braid is more fully treated. The section on the later History of Hypnotism contains an account of the practice of Dr. A. A. Liebeault of Nancy. A section follows entitled "History of My Own Practice." The remaining part of the book is devoted to dissertations on the methods of inducing and terminating hypnosis, susceptibility to hypnosis and the causes which influence it, the experimental phenomena of hypnosis, and the management of hypnotic experiments and an account of the "different stages of hypnosis." The therapeutic use of hypnotism is dealt with in chapters on hypnotism in medicine and surgery and in one on the management of medical and surgical cases. This is followed by a disquisition on hypnotic theories which occupies 150 pages, or nearly a third of the whole work. A chapter is devoted to "the so-called dangers of hypnotism" and this is followed by a summary, conclusion, and list of references. Of the two appendices one is the late Dr. Williamson's account of the origin of Braid's work and the other is a note on spiritualism, clairvoyance, and telepathy.

The general effect produced by the book is a feeling of wonder that such a subject, with all its suggestions of mystery and occultism bred of our imperfect knowledge, can have led to the production of so unstimulating a book. Doubtless Dr. Bramwell was particularly right to treat his subject very seriously, but he might have taken more steps to arouse and to hold our interest. The work would gain much if it were rearranged and rewritten so that the history of the subject and the theories of its various exponents were placed together. For example, the life of Esdaile is given in one place, while his theories will be found in another. The author's views naturally pervade the book, but while lessons from personal experience are of the utmost value in all medical treatises, an author should beware lest the actors of the past should appear merely as puppets in his play. Dr. Bramwell is, we are sure, unaware how strongly the impression is produced that views contrary to his own are erroneous and misleading.

LIBRARY TABLE.

Essays on Rural Hygiene. By GEORGE VIVIAN POORE, M.D., F.R.C.P. Lond., Commander of the Dannebrog; Emeritus Professor of Medicine and Clinical Medicine, University College, London; Consulting Physician to University College Hospital. Third edition. London, New York, and Bombay: Longmans, Green, and Co. 1903. Pp. 426. Price 6*s.* 6*d.*—The first edition of this book was published in the year 1893, a second edition was printed in 1894, and in the present volume the work has been arranged "in more orderly form," as the author says, some omissions have been made, and some new matter has been added. The book as now presented should prove of use to all those who live in rural districts and take an intelligent interest in sanitary matters and it will be found to be suggestive and stimulating. Dr. Poore recommends that the general supply of water in London should be given by meter but he does not apparently take into consideration the cost of the general installation of such a system. In speaking of the old water-supplies of London he says the Westbourne has disappeared and calls Bay's Water a stream. The general teaching of the book, as we have had the pleasure of pointing out on previous occasions, is excellent and its chief use is to show that the sanitation of rural districts must be arranged on plans entirely different from those suitable for towns. Dr. Poore has had considerable practical experience of dealing with human excrement in the country and he is evidently well pleased with the results which he has obtained. He gives, facing the title page.

the reproduction of a photograph of "some results of rural hygiene," which have assumed the material forms of gigantic cabbages and other vegetables. These are from a garden situated in a country town in Hampshire and the author in one of his essays gives the financial results of the sale of such vegetables. These figures would, we think, be more instructive if, in addition to the credit side, cost of labour and so forth were given. A full statement of expenses and profits would make this part of the book most useful.

The Medical Examination for Life Assurance, with Remarks on the Selection of an Office. By F. DE HAVILLAND HALL, M.D., F.R.C.P. Lond., President of the Medical Society of London, Physician to the Westminster Hospital, Physician to the Rock Life Assurance Company. Third edition, greatly enlarged. Bristol: John Wright and Co. 1903. Pp. 112. Price 4*s*.—This little volume will be found of great value to those practitioners who are engaged in medical examination for life assurance. Difficult problems often present themselves which the examiner may find it hard to solve. In Dr. Hall's book many of these are discussed and information is given as to the course which may be adopted in dealing with sub standard lives. There is a tendency at the present time perhaps to underrate the importance of heredity in certain diseases, particularly in the case of pulmonary tuberculosis. The discovery of the tubercle bacillus and the consequent infectious nature of the disease has certainly necessitated a reconsideration of the whole question, but we think there is a danger that the pendulum may swing too far. Possible exposure to infection, as in the case of a brother or sister dying from pulmonary tuberculosis, is, in the opinion of most physicians, of greater import than the death of one parent many years previously to the applicant presenting himself for examination. Dr. Hall is of opinion, however, that given a family history of pulmonary tuberculosis, if the applicant has a well-formed chest, with a weight above the average and has the appearance of robust health, then the life may be accepted at ordinary rates, but if contrary conditions are found then an addition to age will probably be demanded. We also agree with Dr. Hall that too much stress in the past has been laid on the age of the applicant as a factor in deciding whether a family history of tuberculosis should have weight. Statistics show that the death-rate per 1000 from consumption is fairly equal throughout life and that there is no limit as regards age to a person contracting the disease. Interesting observations are also made on the heredity of cancer, diabetes, gout, rheumatism, and insanity. As might have been expected, the attention which has of late years been devoted to the recognition and treatment of appendicitis has been reflected in life assurance. Dr. Hall considers that an applicant who has had a single definite attack which yielded to medical treatment might be accepted after three years' immunity. We believe this period of time to be too short and would suggest that there should be at least five years' immunity. With regard to the vexed question of "functional albuminuria" in regard to life assurance Dr. Hall wisely remarks, "At the present time sufficient data have not been collected upon which to found any definite conclusions." The observations which have been made on individuals who have manifested this phenomenon are of comparatively recent date and the after-history of those subject to this condition has yet to be ascertained. We can recommend a perusal of the work to all who are interested in the subject of life assurance.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., with the coöperation of ADAM SEDGWICK, F.R.S., W. F. R. WELDON, F.R.S., and SYDNEY J. HICKSON, F.R.S. With Lithographic Plates and Engravings on Wood. London: J. and A. Churchill. Vol. XLVII., Part III. December, 1903. Price 10*s*.—The memoirs contained in this part are: 1. On the Anatomy and Development of Distomum Cirrigerum v. Baer, by Ernest Warren, D Sc., of University College, London, with three plates. The encysted and adult trematode was found in abundance in the muscles of a cray-fish which was, it is believed, of continental and probably of German origin. Full and interesting details are given of the distoma at different stages of development so far as, in this specimen, they presented themselves for examination. 2. Studies in the Retina: the Continuity of the Nerves through the Vertebrate Retina, with three plates, by H. M. Bernard, M.A. Cantab. This is the sixth and final part containing the researches of Mr. Bernard on this subject The preceding five parts are contained in previous volumes of the journal. He is not in accord with the statements made by Ramon y Cajal, and now very generally accepted, to the effect "that there are interruptions in the continuity of the cells and their processes in the several layers of the retina" He describes the "ganglionic cells" of the retina as the innermost layer of the retinal nuclei which may or may not have a certain quantity of associated cytoplasm and he denies the existence of the diagrammatic axis cylinder process given off, or supposed to be given off, by these cells He denies also the existence of the "bipolar radially arranged ganglion cells" of the middle layers. He admits the presence of an intranuclear framework of extremely fine fibres, some of which pass from one nucleus to another, establishing intercommunication between them. These fundamental filaments are exquisitely delicate and achromatic. They are capable of conducting nerve stimuli, they are contractile, they can grow, and they can move freely upon one another. They differ from the uniting threads of adjoining nuclei which are short and thick. He terms the plexus of filaments the "protomitomic reticulum." The filaments of the reticulum are associated with chromatin, with a clear fluid matter, with granular cytoplasm, and with the glossy clear threads of the syncytial framework. 3. The Bionomics of Convoluta Roscoffensis, with special reference to its Green Cells, by F. W. Gamble, D Sc., of Owens College, Manchester, and Frederick Keeble, M.A., of University College, Reading, with two plates. The animal here referred to is a green accelous turbellarian peculiar to Brittany. The movements of the colonies of these animals and the causes of those movements are interestingly described. The green colour is due to the presence of cells in the body of the animal; and infection or invasion of the green cells, if it occurs, is by a colourless cell. 4. Trypanosoma in Birds in India, by W. Hanna, M.B., of Liverpool, with a plate. The birds mentioned by the author of this article are pigeons and crows. The trypanosoma is interesting as being found in the blood of patients suffering from sleeping sickness. 5. On the Modification of the Eye Peduncles in Crabs of the Genus Cymonomus, by E. Ray Lankester, F.R.S., with two plates.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Vol. XXX., Nos. 3 and 4. London: C. J. Clay and Sons. Dec. 14th, 1903. Price 10*s*.—The articles contained in this volume are as follows:—1. By J. N. Langley, on the Sympathetic System of Birds and on the Muscles which move the Feathers, with 13 figures in the text. The author of the paper finds that some of the muscles attached to the feathers in birds are definitely erector and some are definitely depressor muscles; both consist of unstriated muscle and their arrangement is complex. He finds also that the spinal sympathetic fibres arise from a restricted region of the spinal cord lying between and slightly overlapping the regions of origin of the nerves to the limbs. The areas supplied by the sympathetic fibres in successive cutaneous branches only slightly overlap The disposition of the muscular fasciculi is given. 2. By H D. Dakin, 1851 Exhibition Research Scholar, the Hydrolysis of Optically Inactive Esters by Means of Enzymes. Part I., the Action of Lipase upon Esters of Mandelic Acid; the Resolution of Inactive Mandelic Acid, with four figures in the text. 3. By J. W. Scott-Macfie, on the Question of Direct Action of Tissue Extracts of Protoplasm. The author gives the results of his experiments on the action of the extracts of the adrenals, pituitary body, ovary, brain, thymus, and other organs on the embryonic heart, on the movements of leucocytes and on cilia. Little or no action was observed. 4. By John Malcolm, on the Influence of Pituitary Gland Substance on Metabolism. 5. By Sydney W. Cole, Contributions to our Knowledge of the Action of Enzymes. Part 2, the Influence of Electrolysis on the Action of Invertin. 6. By H. K. Anderson, M.D., Fellow of Gonville and Caius College, the Paralysis of Involuntary Muscle, with Special Reference to the Occurrence of Paradoxical Contraction. This article deals with the subject of paradoxical dilatation of the pupil and other ocular phenomena caused by lesions of the cervical sympathetic tract, with two figures in the text. 7. By Sydney W. Cole, on Certain Colour Reactions of Proteid due to Tryptophane. 8. By David Fraser Harris, M.D. Lond., on the Hæmoglobinometry and Hæmacytometry of the Blood of the Skate. The proportion of red to white corpuscles is about 12 to one and there are about 10,000 corpuscles to the cubic millimetre in this fish. 9. By Alexander O. M. Fehrsen, M.B., the Hæmoglobin and Corpuscular Content of the Blood of the Newborn. Dr. Fehrsen finds the blood of the newly born has a high percentage of hæmoglobin, a mean of 6,000,000 or a little more of erythrocytes, a well-marked leucocytosis of 18,000 per cubic millimetre, and an invariable presence of nucleated red blood corpuscles up to the third hour after birth. 10. By H. M. Vernon, M D. Oxon., the Peptone-splitting Ferments of the Pancreas and Intestine. 11. By A. E. Boycott, M.B. Oxon., on the Number of Nodes of Ranvier in Different Stages of the Growth of Nerve Fibres in the Frog, with two figures in the text. The volume concludes with the Proceedings of the Physiological Society.

# Analytical Records
FROM
THE LANCET LABORATORY.

(1) "TABLOID" ANTIFEBRIN COMPOUND; (2) TABLOID HYDRARG. PERCHLOR. ET POTASSII IODIDI; AND (3) "SOLOID" HEMISINE.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

1. THE tabloid antifebrin compound embodies an admittedly useful formula for neuralgic affections. Each tabloid contains two grains of acetanilide, one grain of caffeine citrate, and one grain of camphor monobromide. This combination is also stated to be valuable in obstinate cases of vomiting and in sea-sickness. Camphor monobromide is an excellent adjunct in a formula of this description. 2. The tabloid containing one thirty-second of a grain of perchloride of mercury and two and a half grains of iodide of potassium has been prepared in order to supply a convenient means of administering mercury at regular intervals and in small doses. Tabloids containing twice the amount of each of these drugs have been procurable for some time. As illustrating the accuracy of dosage of the tabloid products in general we may add that on analysis we found exactly the amount of drugs respectively represented. 3. Hemisine is the name given to a soloid which contains the principle of the suprarenal gland. This soloid will be found very useful for the hæmostatic and anæsthetic action of its constituent in local applications.

SPECIAL SCOTCH WHISKY.

(FINDLATER, MACKIE, TODD, AND CO., LONDON BRIDGE, S E)

This is a spirit of pale colour possessing only a slight flavour of malt. On analysis it yielded the following results: extractives, 0·09 per cent.; mineral matter, 0·02 per cent.; and alcohol, by weight 41·30 per cent., by volume 48·75 per cent., equal to proof spirit 85·43 per cent. As regards secondary products the following were the results expressed in grammes per 100 litres of absolute alcohol present: acidity reckoned as acetic acid, 12·30; aldehydes, 10·25; furfurol, 0·51; ethers reckoned as ethyl acetate, 5 33; and higher alcohols, 102·50. We do not hesitate to say that according to these results the bulk of this spirit consists of grain alcohol and that little of it is derived from barley malt. This is clear from the fact that the furfurol exists in only very small amount while the ethers and higher alcohols are relatively low. The whisky, however, has evidently been matured in sherry casks, judging from the amount of fixed acidity. Whilst these figures show a very large proportion of grain spirit there is no doubt that the whisky is free from those objectionable products which are removed by age. There is very little malt flavour in the spirit.

STERILISED CREAM.

(FUSSELL AND CO., 4, MONUMENT-STREET, LONDON, E C.)

When submitted to analysis this cream gave the following results: milk fat, 29·45 per cent.; sugar and proteids, 7·50 per cent.; mineral matter, 0·51 per cent.; and water, 62 54 per cent. It contained no preservatives and keeps in the tin satisfactorily. The flavour is that of fresh cream, for it is practically free from that peculiar taste which sterilisation by heat commonly produces. This cream satisfies critical examination as regards taste, analysis, and preservation.

PHYSIOLOGICALLY PURE SALICYLIC ACID PREPARATIONS.

(R W. GREEFF AND CO., 20, EASTCHEAP, LONDON, E.C.)

It has long been recognised that preparations of salicylic acid should be physiologically pure—that is to say, should not contain impurities which by reason of their toxic action render the preparations unsuitable for medical use. The introduction of the artificial acid made by acting on phenol with carbonic acid early sufficed to show that there were certain toxic phenol derivatives present which gave rise to objectionable physiological effects. This objection to the artificial acid has been removed by greater attention being paid to the processes of purification. We have received from the above firm four preparations which have been prepared with the utmost care so as to exclude all impurities. The physiological action of the product is thus due to pure salicylic acid itself. The preparations are salicylic acid powder and crystals and salicylate of soda also in powder and crystals. All these preparations respond favourably to laboratory tests. They are perfectly clean and well crystallised. In prescribing salicylic acid and its compounds only preparations of the degree of purity thus indicated should be employed. We have also received a sample of salol from the same makers which also gives evidence of perfectly pure materials having been used and of a process having been employed which yields a pure, clean product. These fine drugs are prepared by the Société Chimique des Usines du Rhône at St. Fons, near Lyons.

MAXIM ALE.

(C. VAUX AND SONS, THE BREWERY, SUNDERLAND.)

The analysis of this beer was as follows: alcohol, by weight 4·62 per cent., by volume 5·78 per cent., equal to proof spirit 10·13 per cent.; extractives, 5·01 per cent.; mineral matter, 0·22 per cent.; and sugar malt, 1·99 per cent. The beer was in sound condition and contained only a minimum of acidity. It appears to come midway between stout and light ale. The beer is somewhat "dry" to the taste owing probably to the relatively small amount of sugar which it contains; the deficiency is made up by a notable proportion of dextrin. The colour of the beer resembles that of brown Munich beer As it is only mildly bittered this beer would be more dietetically suitable for some individuals than heavy stout or ale.

(1) HOPOGAN; AND (2) EKTOGAN.

(The British Druggists, Limited, 85, Clerkenwell road, London, E.C)

Hopogan represents a peroxide suitable for internal administration and ektogan one for external use. The former contains peroxide of magnesium and the latter peroxide of zinc. According to our analysis hopogan contains 14·60 per cent. of magnesium peroxide, which is equivalent to 4 17 per cent. of available oxygen. Ektogan according to our analysis contains 41·40 per cent. of zinc peroxide which is equivalent to 7 per cent. of active oxygen. It is suggested that magnesium dioxide is useful in cases of deficient oxidation of the blood, while the fact that by interacting with the gastric juice peroxide of hydrogen is developed would suggest that fermentation of the gastric contents might be arrested. Clinical cases are cited in support of the favourable action of hopogan in these respects. Zinc peroxide is similarly regarded as an excellent antiseptic application in dermatological practice and in the treatment of wounds. Both preparations are of a very interesting kind and worthy the attention of our readers.

ROYAL DOUBLE CREAM CHEDDAR CHEESE.

(The Somerset, Dorset, and Devon Dairy Co., Limited, Chard, Somerset.)

Our analysis of this cheese was as follows: moisture, 35·24 per cent.; mineral matter, 3·84 per cent.; fat, 38 85 per cent.; and proteid, 22 07 per cent The cheese has an excellent and attractive flavour recalling that which has made real English cheddar famous. Nowadays the fact that a cheese is made entirely from milk is something for which to be grateful.

VOICE PASTILLES.

(Barker and Dobson, Franklin place, Whitefield road, Liverpool)

We have examined these pastilles and find that the materials employed are of satisfactory quality. The pastilles are demulcent and antiseptic They have a soothing effect. They are useful for relieving sore and irritable conditions of the throat. The formula is an excellent one.

COCOA ESSENCE.

(Cleeve Brothers, 22, Sir Thomas street, Liverpool.)

This is a pure unsophisticated cocoa containing, according to our analysis, 30·80 per cent. of the fat of the nib. The mineral matter amounted to 5·40 per cent., which showed an alkalinity expressed in terms of potash of 1·20 per cent. The moisture amounted to 5·90 per cent. This cocoa is of very good quality and gives a satisfactorily uniform decoction.

(1) BIEDERT'S MILK FOR INFANTS ("CREAM MIXTURE"); AND (2) BIEDERT'S SOMATOSE MILK FOR INFANTS AND INVALIDS.

(A. Prinzen and Co, Soetermeer, Holland Agency: Messrs. Burgoyns, Limited, India Buildings, Akers-street, Manchester)

1. According to our analysis the cream mixture gave the following results: moisture, 31·20 per cent.; mineral matter, 1·70 per cent.; proteids, 16·75 per cent.; fat, 13·71 per cent.; and milk sugar, 36 64 per cent. The preparation is thus seen to be not lacking in any particular element for the purpose of infant feeding. On diluting suitably with water a preparation may be obtained approximately representing the composition of mother's milk, for which it seems to be an excellent substitute according to the testimony of a number of German physicians. The food is retained well in many cases in which cow's milk is inadmissible. It is sterilised and keeps satisfactorily in the tin. 2. Somatose milk gave the following results on analysis: moisture, 33 39 per cent.; mineral matter, 1·58 per cent.; proteid, 14·99 per cent.; fat, 18·71 per cent.; and milk sugar, 31·33 per cent. As a preparation for infants and invalids this food has the advantage of containing a soluble and easily assimilable proteid. For use it is to be diluted with water in the same way as the previous preparation. Somatose milk is also sterilised in the tin but on exposure to air a discolouration set in probably owing to the interaction of the somatose. This detracts somewhat from the preparation unless it is used immediately after the tin has been opened.

HETRALINE.

(Charles Zimmermann and Co., 9 and 10, St. Mary-at-Hill, London, E C)

Hetraline is described as a new derivative of hexamethylene tetramine which in its action is similar to urotropine and helmetol when employed in the treatment of gonorrhœa. It is stated that in daily doses of from one and a half to two grammes, given after meals, this drug is well borne by the gastro-intestinal tract and the urinary passages and that in acute gonorrhœa the pain and strangury disappear and the urine becomes clear.

PURE GRANULATED CHOCOLATE.

(J. J. Provoyeur, Gand, Belgium, and Howell Bros. and Co, 20, Lombard street, London, E C)

Chocolate in a fine granulated form is somewhat of a novelty. In the preparation above described the granulation and dryness are evidently effected by employing a somewhat large proportion of cane sugar. In our opinion the chocolate is too sweet owing to this excess of sugar. A cup of chocolate may be very quickly prepared from this granulated powder. According to our analysis the powder contained: moisture, 2 40 per cent.; mineral matter, 1·40 per cent.; fat, 21·60 per cent.; sugar, 66·89 per cent.; and cocoa principals, 7·71 per cent. The chocolate is manufactured without any addition of alkali, as shown by an examination of the mineral matter. The cocoa flavour is decidedly good.

INDIA PALE ALE

(Warricks and Richardsons, Limited, The Brewery, Newark-on-Trent)

Our analysis of this beer was as follows: alcohol, by weight 6 57 per cent., by volume 8·18 per cent, equal to proof spirit 14·35 per cent.; extractives, 4·03 per cent.; and mineral matter, 0 26 per cent. The beer was sound and free from undue acidity. Though "full bodied" it is not heavy but refreshing and without that tendency to produce drowsiness to the same degree as do the heavier kinds of malt liquor. It is stated that care is taken so far as possible to suppress the development of higher alcohols during the fermentation.

PAUTAUBERGE'S SOLUTION.

(L. Pautauberge, Paris, and Wilcox, Jozeau, and Co., 49, Haymarket, London, S.W)

Each tablespoonful of this preparation is stated to contain ten centigrammes of pure beechwood creasote and 50 centigrammes of hydrochloro-phosphate of lime. The combination of the hydrochloro-phosphate of lime with the creasote is regarded as rendering the creasote better tolerated than when it is exhibited in the ordinary manner. This solution is said not to irritate the gastric mucous membrane and to have been used with favourable results in the treatment of tuberculosis. We have confirmed the presence and amount of the medicinal agents indicated.

(1) B B SMOKING MIXTURE; AND (2) LUMLEY MIXTURE.

(Bartlet and Bickley, 17, Brook street, Bond street, London, W.)

Both these tobacco mixtures gave no evidence on examination of objectionable manipulation. The aroma and flavour are due entirely to pure tobacco; no foreign scent has been added. The proportion of the kinds of tobaccos used is such that the smoke yielded is cool and pleasantly aromatic.

THE LANCET.

LONDON: SATURDAY, JANUARY 2, 1904.

The Public and the Medical Profession.

The beginning of the year is naturally made a season for moralising and we claim indulgence for a few words of serious reflection upon the relations now existing between the public and the medical profession. Each New Year's day is a milestone at which we pause, now to look back on the road already covered and now to look forward at the track stretching ahead. Instinctively we try to presume the future from the experiences of the past. Part of such a necessary review of the position of things medical we have already presented to our readers, for in the Annus Medicus, published in the last number of the old year, will be found a summary of the medical events of that year as they have been recorded, collated, or commented upon in our columns. It remains to surmise what are the directions in which medical advances may be expected during 1904, while assuring our readers that no efforts will be spared on our part to assist the cause of progress. It is particularly desirable that we should be able to anticipate in thought the more important medical and professional tendencies, for, as we have frequently insisted, the work of The Lancet is essentially coöperative. We can only give to our readers the latest medical learning and the most practical professional information if we, in our turn, are helped by our readers. All editorial efforts would be futile if we did not find among our public many willing and happy to communicate through us with their professional brethren, thus rendering our pages a bureau for the collection and redistribution of knowledge. It is valuable, therefore, that our many collaborators should know the directions in which useful developments, whether scientific or professional, may be looked for. It is generally impossible to say that any one pathological fact contains a more useful lesson than another, or that one question in medical ethics has a deeper sociological significance than another; and it is not in any such manner that we would attempt to prophesy what new theories or what illuminating deductions may be awaited. But it is not impossible to indicate what are the prevalent conditions of scientific research or how the cause of the medical man, as a professional man, can best be served.

We think that the most noteworthy sign of the times in regard to medicine is the enormous interest that is taken by the public in affairs that were wont at one time to be regarded as purely medical. This is the particular difference to be observed nowadays both in the discussion of purely scientific questions and in the consideration of medical politics; and everything points to the fact that the fusion of medical and public interests will become closer during the succeeding years. A sanatorium for the prevention and curative treatment of consumption is rising under the direct eye of His Majesty the King, paid for by a layman, and constructed in accordance with the choice and directions of a committee which is partly composed of laymen and in the hands of which the management will later be vested. Yet medicine is adequately—the public might even think preponderatingly—represented at every step of the proceedings. Research work into the origin of cancer is being busily pursued with funds largely subscribed by the public, and if the bulk of the investigations naturally falls to pathologists the help of all scientific students is freely demanded and acknowledged. It must be observed, too, that the funds are being subscribed not by an ignorant public who think that a certain sum of money being paid certain results must automatically follow, but by a thoroughly intelligent public, again with the King as the dominant spirit, who have grasped the point that definite knowledge must not be expected too soon, or indeed at any fixed period, from such labours as those undertaken by the workers in the pathology of cancer. No one knows in which direction a profitable start may be made for such investigations, and here it is well to say that great issues must not be attributed to the fact that certain carcinomata, and new growths which have been very generally classed as carcinomata, exhibit retrogression under treatment with radium or the x rays. The progress in therapeutics thus implied is most important, and undoubtedly during the year now begun medical practitioners will mutiply their observations and experiments along this line; but the public ought to understand from them that many of the claims made for the treatment of cancer by the x rays and by radium are as yet unproved. That certain cases have derived benefit is sure, and just so sure is it that no general therapeutic law has been revealed for the remedy of cancer. We need hardly multiply instances to prove that the public at large are aroused to a sense of the responsibilities of medicine and of the debt that is owed to our profession. Contributions to the hospitals on a scale of munificence which grows steadily highe are chronicled week by week; the daily papers a full of correspondence showing an almost embarrassin interest in the affairs of the same institutions; tropic medicine is recognised as an adjuvant to Imperial expan sion, and hygiene is now steadily preached from pulpit The ignominious end to an eccentric onslaught made by th National Antivivisection Society upon the work of certai physiologists showed the sensible public to be ranged a one man on the side of the cause of true medicine. It i unnecessary to say more to show that in 1904 the medica profession in this country will be carrying on their work in an environment which, despite occasional appearances, will be favourable to the growth of medical science.

The lesson from all this we take to be that the medical profession would often be well advised to invite the public more into their confidence. This country has, during the past quarter of a century, been transformed by education, so that the public are able to appreciate the reasons for scientific proceedings in a way which they could not have possibly done in the days of our fathers. Much medical research is the pursuit along specialised lines of general scientific procedure; many therapeutic measures are but a particular application of a common knowledge of chemistry or some ancillary science. When there were but three learned professions, and when a large proportion of the public was completely illiterate, no good purpose was served by any attempt on the part of the medical man to explain his actions. No member of the laity would have understood the elements of what he proposed to talk about. But now that medicine touches the borders, or passes over into the territory, of so many other sciences, and now that none of the public can be called completely illiterate, while a large proportion of them enjoy as good education as the average medical man, there is no need for the medical man to feel that he cannot discuss a professional topic with a layman. We are not advocating the publication by medical men of popular views on disease in the daily press—such unprofessional action is open to grave abuses and occasionally does serious harm. But we are suggesting that medical men should be quick to seize on this assistance of laymen, which events prove can be obtained if it is intelligently sought. The sympathy of the public need not be expressed only by the support of large educational schemes or the erection of splendid buildings. The payment of medical men for the discharge of State or municipal duties, the fees of medical witnesses and public vaccinators, the position of medical men working for provident institutions—we quote these as a few examples—are subjects in which our profession and the public have equal interests. On the surface these interests may be opposed, but frank discussion between intelligent men would soon show on which side justice lay. It is this *entente cordiale* that we would urge our readers to cultivate during the year now opening.

Plague Research in India.

IN all schemes for the improvement of the public health, and especially for the prevention of epidemic disease, there can be little success unless the general population cooperates with the sanitary authorities. A convincing proof of this is to be found in the behaviour of plague in Asia and Europe respectively, for in India and China it has caused an enormous annual loss of life for the last seven or eight years, whereas in European maritime countries the landing of plague patients from vessels coming from Indian ports has never been followed by any considerable extension of the disease. Differences of climate do not account for this recent immunity of the western nations, for all regions of Europe except the most northerly have been the scene of devastating epidemics at intervals during the last 600 years. In Europe, however, the idea has always been held that protection was to be obtained by interposing some barrier between the sick and the healthy. In former times it was hoped that this could be accomplished by rigorous quarantine and by military cordons round infected towns; many persons also, where circumstances permitted it, deserted their homes at the first alarm of plague and lived elsewhere till the danger was past. In modern times the underlying idea is the same but the method of applying it is so much improved that for practical purposes the old routine of quarantine has ceased. The whole question has passed into the hands of the medical profession who rely, for the safeguarding of the public, on early diagnosis of the disease and prompt removal of the patient from his home to an isolation hospital. At the same time the place which he has occupied is disinfected and all persons who have been exposed to infection are kept under constant observation until the period of incubation of the disease has expired. In India this system fails entirely, for the apathy of the population and their dislike of European interference lead to wholesale concealment of the presence of the disease and to murderous attacks on the sanitary officials with occasional rioting on the removal of a patient to a hospital. Dr. YERSIN, as is well known, established the fact that an attack of plague is due to invasion by a specific bacillus, the microscopic recognition of which either in the actual patient or after cultivation or inoculation forms the basis of the modern diagnosis of the disease. There are, in fact, only a few other diseases the presence or absence of which can be determined with similar rapidity and precision. Much, however, still remains to be done in explaining the etiology of plague and some printed reports which have reached us show that Dr. J. A. TURNER, executive health officer of Bombay, has been recommending that competent bacteriologists should be encouraged to study the relation of plague outside the body to the organism which is associated with the disease in its clinical aspect The frequent occurrence of plague in the lower animals shows that the human subject is not the only host of the specific bacillus, and Dr. TURNER believes, no doubt with perfect correctness, that light might be thrown, by investigation in this direction, upon the prevalence of plague in India. Dr. TURNER'S suggestions, made to the municipality of Bombay, were eventually submitted to the Governor of the Presidency, who approved of them so far that in the beginning of November certain appointments for the purpose of facilitating the proposed research were announced, but since that time nothing seems to have been done. Considering that hitherto all attempts to check the disease in India have yielded almost no result it is obvious that every effort of whatever kind should be made to throw more light on the pathology and propagation of plague. But the serious question of inducing the population to acquiesce in sanitary precautions will still remain, and for this dilemma there would seem to be no remedy.

The Functions of the General Medical Council.

NOTWITHSTANDING much that has been written and printed at various times with regard to the powers, the duties, and the responsibilities of the General Medical Council, we frequently receive evidence that these are not so correctly understood in the profession as they should be. Letters often reach us describing possibly some serious abuse or some crying evil and indignantly inquiring why the Council permits this, that, or the other subject of complaint, or why the Council does not put a stop to the conduct, of whatever nature, that is impugned. A letter of this sort, under the title that appears above this article, will be found on page 55; and as we fully believe the writer's statement that his mental attitude is that of many other medical men we think it will be useful exactly to define, not for the first time, what are the functions of the General Medical Council. Generally speaking—and it is the case in regard to the subject of "M.D. Cantab.'s" letter—the Council has no more power in the matter complained of than the complainants themselves, who frequently appear to think of it very much as the average Frenchman was once supposed to think of the "Lor' Maire." Its actual authority is derived from a small number of very simple enactments and does not extend beyond their purview. It is authorised to keep a medical register, intended to enable the public to distinguish "qualified from unqualified practitioners," and containing the names of all persons who are legally qualified medical practitioners and who, by virtue of their registration, are entitled to recover their professional charges in a court of law, to give valid medical certificates, to appear as medical witnesses, and to hold various offices or appointments. It has no discretion with regard to registration, but is bound to insert the names of all applicants who are provided with one or more of the diplomas or licences specified in the Medical Acts. It is authorised to remove from the Register, and thus to deprive of the above-mentioned legal privileges as practitioners, any persons who are convicted of crime or misdemeanour, or who may be adjudged by the Council itself, after due inquiry, to have been guilty of "infamous conduct in any professional respect." It is authorised to require from any of the licensing bodies information with regard to the courses of study and examinations to be gone through in order to obtain their respective registrable qualifications, to visit and to inspect the examinations, and in the event of considering the courses of study and the examinations insufficient to secure the possession by the persons obtaining the qualifications of sufficient knowledge and skill for the efficient practice of their profession, to "represent the same" to the Privy Council, which is then empowered to take such action as may be necessary. The Council is also authorised to make representations to the Privy Council on one or two other comparatively unimportant matters and to prepare and to publish a Pharmacopœia. In these few sentences the whole of its actual powers are described, but it has frequently been called upon as a medical body established by Act of Parliament to advise Government departments with reference to intended legislation. It was thus called upon in relation to the Midwives Act and was compelled to hold long and expensive meetings in order to reply to inquiries which were addressed to it by the Privy Council. In other words, the Privy Council obtained *from it a good* deal of gratuitous medical advice, the cost of affording which was defrayed from the fees paid by practitioners for registration. As these fees would come from the pockets either of the newly qualified men or from those of their parents, it may be said that the work of medically advising the Government has been entirely paid for by the medical profession—an arrangement which seems hardly consonant with what lawyers would describe as "natural justice."

The disciplinary powers of the Council with regard to the conduct of medical practitioners are both less extensive and less elastic than those of the Royal Colleges; and having been designed only for the protection of the public, are of very slight avail for the protection of the profession. The legislature evidently contemplated the possibility of conduct on the part of a practitioner which might be insufficient to bring him within the grasp of the criminal law, and yet sufficient to show his absolute unfitness to be trusted with professional opportunities and responsibilities. The Council was empowered to erase the name of such a person from the Register—that is to say, to deprive him absolutely and permanently of any legalised medical status or of any power of legally earning his living as a medical practitioner. No power of restoration to the Register was conferred. The result was, of course, that the Council shrank from taking the extreme step of erasure in any but very gross cases, and that others were left practically unpunished; while some of those whose names were erased appealed to the Courts and obtained judicial decisions as to the way in which the words "infamous conduct" should be interpreted. In 1862 the Council was made a corporation by a separate Act of Parliament, and thereafter, taking advantage of the general power of a corporation to review or to rescind its own decisions, it commenced the practice of restoring to the Register, after a certain period, names which had been erased from it. In this manner it obtained and exercised what is practically a power of suspension from professional privileges, although it is very doubtful whether the restorations thus effected would be sustained by the courts if the question were tried. A still further modification of procedure, with a great consequent increase in the power of the Council to deal with minor cases of professional misconduct, was suggested by Mr. BRUDENELL CARTER who obtained the passage of by-laws under which the Council, after hearing a charge and the defence, became able to postpone its verdict upon the case to a future session. It stopped short of pronouncing the proved conduct to be "infamous," a pronouncement which would have necessitated removal from the Register, and said to the defendant that he would do well to reconsider his course of action, and to come before the Council again in a position to show that he had abandoned it. In this way a moral suasion in excess of the statutory power was exerted; and many men who could not have been removed from the Register without great risk of the decision being reversed by the King's Bench were induced to abandon objectionable courses, such, for example, as the holding of undesirable appointments under touting benefit societies. In these two directions therefore the Council may be said to have strained its powers for the protection of the profession, but it still has no means at *all of* dealing with ethical questions as opposed to absolute misconduct. The Royal Colleges, on the other hand, have great powers if they choose to exert them, and it is to them rather than to the Council that the profession should look for the regulation of conduct in comparatively minor matters. The Colleges are able to withdraw their diplomas for any cause which they may consider sufficient, and their decisions are neither subject to the review of any other tribunal nor hampered by phrases such as "infamous conduct," which require to be technically interpreted by legal decisions.

It will be seen from this summary of the important but limited functions of the General Medical Council that the Council was established entirely for the protection of the public and that, instead of having been supine in the matter of protecting the profession, it has actually gained some limited power in this direction by means which may almost be described as a straining of its statutory authority. It has no mandate or powers whatever to prevent the evils of quackery to which "M.D. Cantab." alludes. In relation to the licensing corporations and to their requirements from candidates for qualifications it is almost, if not altogether, powerless. It has the right to visit and to inspect their examinations, but, if it is not satisfied, all it can do is to report "insufficiency" to the Privy Council, and the Privy Council would then hear the case and decide upon it, according to its lights. The corporations, if their actions were impugned, would, of course, defend themselves; and the practical result would be a trial, with a conflict of expert testimony, after hearing which a few lawyers would be called upon to give a binding decision upon medical questions concerning which they would be profoundly ignorant. Whether such a decision were in favour of the Council or of the corporations it could hardly fail to be derogatory to the dignity and prejudicial to the interests of medicine, and it may well be hoped that no occasion will arise for its being pronounced. The corporations may be expected to recognise before long that their own best interests are inseparably bound up with the maintenance of a high professional status and that this can only be effected by the maintenance of a high standard of education.

Annotations.

"Ne quid nimis."

THE IRISH POOR-LAW MEDICAL SERVICE.

The recent suggestion of Sir Lambert H. Ormsby, President of the Royal College of Surgeons in Ireland, that the medical officers of the Poor-law service should be chosen by competitive examination, although it has been often made before, has raised considerable discussion. Mr. J. S. McArdle, another Dublin surgeon, as reported in The Lancet of Dec. 12th, 1903, p. 1694, objects to this plan on the grounds that it would interfere with the privileges of local government and that it would be "contrary to the spirit of the age." To this the President of the Irish Medical Association (Dr. L. Kidd of Enniskillen) replies advocating that the service should be made a State one (like the naval and military medical services) and that the Treasury should find the money for the whole of the medical officers' salaries. The present arrangement for the election of Poor law medical officers is a deplorably bad one. They are not now elected on the ground of merit alone, but religion, politics, and acquaintance with the local guardians are the factors that weigh in determining a candidate's selection. In these circumstances is it any wonder that the service is gradually deteriorating, that the able young men of the medical schools refuse to enter it, and that as a natural result the problems of hygienic and preventive medicine (which are more pressing in Ireland than in any other part of the United Kingdom) are totally neglected? The dispensary medical officers are the sanitary authorities of their own districts but if they encounter glaring hygienic defects how can it be expected that they can take action when these conditions are present in the houses or farms of the people who appoint them? Recently at Sligo the Local Government Board inspector reported that he found the houses in which an epidemic was raging "perfectly indescribable with filth" and, as pointed out by Dr. Kidd, these words are unfortunately applicable to many parts of rural Ireland. Mr. McArdle forgets that the Irish Poor-law medical service is to a large extent already a State service, for it is a fact that no medical officer can be appointed or dismissed, no salary can be fixed, raised, or lowered, and no locum-tenent can be employed without the sanction of the Local Government Board. Further, the duties of the medical officers are drawn up by the Local Government Board and not by the guardians and the recommendations of the medical officer, if neglected by the guardians but approved by the Local Government Board, may be executed in spite of the guardians. The Local Government Board has the power, which it has been obliged to exercise on several occasions, of dissolving a recalcitrant board of guardians and of appointing officials of its own to discharge the duties of these guardians. Popular election of medical dispensary officers in Ireland is not a success and it would, in the opinion of many men of experience, be a much better plan and would in the end do away with the present deplorable state of the Poor-law medical service if it were made a State one on exactly the same basis as the medical services of the navy and the army. Entrance would then be by examination, promotion to higher posts, such as medical inspectorships and the like, would be made on evidence of efficiency and there would be superannuation with retirement at the usual age limit (65 years). It is perfectly absurd to speak of such a change being "contrary to the spirit of the age." In Ireland at the present moment, as we have said, religion and politics, not efficiency, determine the election of nine-tenths of the dispensary medical officers of that country. The true "spirit of the age" is to put a stop to such eighteenth century practices and to make efficiency alone the test of the appointment of those who are to attend on the poor, and this we believe can only be brought about by making the Poor-law medical service of Ireland a State one and by freeing it from the present baneful influences which are degrading it to such a level that soon no self-respecting man will enter it.

THE LATE REV. S. A. THOMPSON YATES.

A few lines of recognition—he would himself have cared for no more—are due to the memory of the Rev. Samuel Ashton Thompson Yates whose recent death has already been announced in our columns. He was known as a wise and munificent supporter of the interests of medical science but his gifts were for the most part anonymous and no one in all probability is in a position to enumerate them. The exceptions to his general rule of anonymity were his presentation to the University College, Liverpool, of the laboratories known as the "Thompson Yates" Laboratories and his donation of scientific literature to the Medical College of the London Hospital known as the "Thompson Yates" Library. The laboratories at Liverpool for the study of physiology and pathology were erected and supplied with apparatus at a cost of upwards of £30,000. They are unrivalled for their purposes by any laboratories in the United Kingdom and are probably not surpassed by any of the great laboratories of the continent or in America. They were opened in 1898 by Lord Lister, the occasion being made remarkable by the presence of Professor Virchow and a very distinguished gathering of medical men. The

Thompson Yates Library of foreign literature for the use of the Medical College of the London Hospital contains the chief foreign periodicals dealing with anatomy, physiology, and pathology, which were collected at a cost of nearly £1000. "Mr. Thompson Yates," writes a well-informed correspondent, "had a deeply-rooted abhorrence of fashionable philanthropy; his calm and enlightened judgment favoured objects which to common minds were not attractive and popular. He conceived the idea that the scientific side of hospital work was apt to be starved for the charitable side, and with this view he gave to the Medical College of the London Hospital considerable sums of money for the purchase of instruments and apparatus for the departments of physiology, advanced anatomy, embryology, and bacteriology. Within the last few months of his life in the same conviction that specialised knowledge and not sentiment was the need of the age he gave a large sum to promote the teaching of economics to one of the colleges of the University of London. Mr. Thompson Yates lived for some years at Mile-end and acquired a thorough insight into the social and charitable affairs of the district. He was a guardian of the poor, a member of the infirmary committee, and he was also a member of the Asylums Board for six years, during which period the metropolis was visited with two severe epidemics of small-pox. He took an active interest in the Poor-law schools, in the Tower Hamlets Pension Fund, and the East-end Nursing Association. In all that he did, in all that he gave, he was one of those who 'consider' the poor." Our correspondent's just remarks on the useful and unostentatious career of a good man will be read with interest by many of our readers to whom Mr. Thompson Yates was merely known by name as the munificent benefactor of the Liverpool Medical School.

THE PATHOLOGY OF THE BLOOD IN GENERAL PARALYSIS.

THE blood of patients suffering from dementia paralytica has been the subject of microscopic study by many observers for 20 years past but no regular and systematic investigation extending over a considerable portion of the course of the disease is known. A study undertaken with such an object in view was carried out during the past two and a half years by Dr. A. R. Diefendorf, lecturer on psychiatry at the Yale University Medical School, and an account of the results obtained is published in the *American Journal of the Medical Sciences* for December. Passing over the earlier studies on the blood of paretics made by Erlenmeyer (1846), Sutherland (1873), and Voisin (1879) with instruments which did not give results comparable with our own, we come upon the work of MacPhail (1884) who in his study of 15 cases of general paralysis discovered that the hæmoglobin and erythrocytes were relatively low in the first stage of the disease, increased slightly during the quiescent period, and diminished greatly during the final stage. He also found that the leucocytes increased proportionately toward the end of the disease and that states of excitement were associated with changes in the condition of the blood. Further detailed and concordant observations of the hæmoglobin percentages in various stages of the disease were published by Thompson (quoted by MacPhail) and Bevan Lewis (1889). More recent blood examinations of general paralysis have been made by Smyth (40 cases of general paralysis), Winkler (four cases), Kryspiakiewicz (15 cases), Roncoroni (15 cases), Capps (19 cases), and Jeliffe (17 cases) during the period 1890 to 1897 and a number of interesting facts have been ascertained. Dr. Diefendorf's studies were carried out on 11 patients with the following results. The blood examinations were made weekly, at the same time of day, and all the patients were on uniform diet. The erythrocytes and leucocytes were counted with a Thoma-Zeiss hæmocytometer and the hæmoglobin was estimated with a Fleischl's hæmometer. The hæmoglobin in all cases, says Dr. Diefendorf, showed a moderate anæmia which became more marked but never profound—i.e., below 65 per cent.—as the disease advanced. During the terminal stage the percentage of hæmoglobin was from 3 to 20 per cent. higher than that of the stage just preceding. The hæmoglobin during the various paretic states of quiescence, of excitement, and of stupor, not terminal, presented no constant or characteristic change. There was no increase in the percentage of hæmoglobin during the quiescent period when nutrition regularly improved. The erythrocytes in eight cases investigated during a period of many months showed normal proportions which sank to subnormal for a short period just previous to the stage of terminal dementia. In the latter stage the percentage rose again to the normal. This rise "was exactly coincident with the beginning of the terminal state" in five of the ten cases. The various paretic states, exclusive of the terminal state—viz., those of excitement and stupor—failed to exhibit any change in the erythrocytes. As regards the relation between bodily nutrition and the erythrocytes the latter gradually diminished in numbers as the disease progressed and nutrition was impaired, but in the terminal state of dementia, when there was a considerable loss of bodily weight, there was a marked increase in the number of red corpuscles. No appreciable changes could be observed in the erythrocytes at the time of, or immediately after, paralytic attacks. As regards the leucocytes the number and characters of these elements varied irregularly during the early and intermediate stages. But in all cases a rise in the number of leucocytes which amounted to slight or moderate leucocytosis occurred with the onset of terminal dementia. This leucocytosis varied from 10,700 to 27,000. Special states of excitement or stupor, apart from the terminal state, were not associated with any characteristic leucocytic changes. Plasma cells were carefully looked for in the differential counts but were never encountered. This observation is of importance because of the prominent rôle played by these cells in the vascular changes in the brain which have come to be regarded as a pathognomonic condition. The anæmia which occurs in general paralysis is, says Dr. Diefendorf, similar to that which accompanies chronic diseases, as chronic nephritis, cirrhosis of the liver, and syphilis, except that it is less pronounced. It is in accord with the progressive atrophy of the nervous system, accompanied by a gradual and complete loss of function as well as atrophy and arterio-sclerosis of the internal organs. The tendency for this anæmia to disappear and to be replaced in the terminal state by a progressive increase in both red and white corpuscles which in some cases passed the normal limits does not, so far as recorded, find its counterpart in other diseases and is most difficult of explanation. The presence of the leucocytosis accompanying paralytic attacks has already been established by Capps as being in harmony with the toxæmic theory, a view supported by the later studies of Kroubmiller, Pugh, and Diefendorf himself.

MORTUARIES.

IT is well known that many of the metropolitan mortuaries are very far from being what they should be. We have upon many previous occasions, notably in our issues of April 3rd (p. 972) and April 17th (p. 1105), 1897, called attention to the lack of proper mortuary accommodation and also of proper coroners' courts. Only recently Dr. F. J. Waldo, the coroner for the City and for Southwark, has been complaining of the lack of accommodation afforded for the holding of inquests in the latter borough. With regard to mortuaries we are willing to allow that some boroughs—for instance, Kensington and Chelsea—have properly appointed airy buildings where the dead may rest before burial and where there is also every facility for making post-mortem examinations decently and in order. But other boroughs are not so fortunate and in poor and densely populated parishes there is a natural disinclination on the part of the relatives of the dead to allow the body of one whom they have lost to be taken out of the house until the time for the funeral. We are aware of cases in which corpses have been kept in coffins for some days in rooms about nine feet square which were occupied night and day by four or five persons. This is not conducive to either health or decency and yet we can sympathise with the dislike, foolish though it be, which is felt in sending the body of a relative to the "parish" mortuary, even when this is a decent building. But a mortuary attached to a parish church is a different thing. Here is no question of rates, or of parish relief, or of inquests, but a quiet and restful place where the body may lie until burial. The vicar of St. Matthew's, Westminster, is at present endeavouring to build a mortuary in connexion with his church. The present Westminster mortuary is an unlovely building in the Horseferry-road and is but little used. Anyone who knows how poor are streets such as Great Peter-street will see that there is need for some place where the inhabitants may lay their dead while awaiting burial. However careless in churchgoing is the average Londoner, yet the poorest among them like to be married and buried by "the Church," and we are sure that if the mortuary can be built it will profit the neighbourhood, *not only from the point of view of* increasing reverence for the dead but from the still more important point of view in one sense, namely, that of preventing infection and of raising the standard of hygiene, for we think there is no doubt that it will be used with gratitude. If any medical men or their patients have any money to spare it will be gratefully received for the building fund by the Rev. W. B. Trevelyan, St. Matthew's Clergy House, Great Peter-street, Westminster.

THE MILK-SUPPLY OF MANCHESTER.

From time to time severe statements have appeared in the press as to the Manchester milk-supply. Recently Mr. James Sadler, secretary to the Cheshire Milk Producers' Association, gave an address on the subject at a meeting of the Ancoats Healthy Homes Society. He took, of course, the rôle of counsel for the defendant but gave some interesting facts as to the number of cows—from 15,000 to 20,000—required to supply Manchester and Salford. At present some 1400 cows are kept in the city. It would be better if they were away, for not only is the space occupied by them required for the population, as Mr. Sadler observed, but in the country they are in more natural and healthy surroundings. He objected to a statement by the veterinary inspectors of the Manchester corporation that "the milk trade is in a filthy condition" and also to an article in the *Manchester City News* which certainly does not lack "local colour." It contained the following passage: "Before it reaches the consumer the milk is handled by milkmen with dirty hands and clothes; it stands in hot and dirt-laden shippons. It is exposed to various blends of more or less polluted air and it is perhaps left for hours in unwashed pails at wayside stations, and all the while the bacteria are breeding by the million, spreading scarlet fever, diphtheria, typhoid, and other diseases." Another paper said: "The appalling child mortality that is directly traceable to the consumption of impure milk must be stayed at any cost." Mr. Sadler said that "having an accurate knowledge of the conditions under which milk was produced in Cheshire he could only characterise these statements as gross and mischievous libels." To prove this he stated that, whereas in 1892 and 1893 there were at Bradford in Yorkshire 10 per cent. of adulterated samples and last year only 2 per cent., in Manchester in the same period the adulteration had gone down from 6 to 3 per cent. This, however, does not meet the charges of want of cleanliness in dealing with the milk, and that there is too much ground for them is clear from the dispassionate statements in Dr. J. Niven's last report on the health of Manchester. Too often, no doubt, "the cowsheds are dirty, as are also the flanks and udders of the cows. The milkers do their work with unwashed hands. Insufficient care is taken in cleansing the milk cans and churns." To remedy these defects the sanitary authority sends a carefully drawn up memorandum giving suggestions and advice which would if followed soon raise the milk-supply above reproach. The cows kept in Manchester are in the majority of cases well fed and groomed but the sheds are sometimes overcrowded. Mr. Sadler with some justification blames "the crude and unsuitable arrangements" of the railway companies, and no doubt they might be improved. He also suggests that the health authorities should see that the arrangements for storage in the town are improved. He asks how it is, if the high death-rate of the children is due to the milk, that it is lowest in the districts using most milk and highest where the least is used. Though it is evident that the milk-supply of our large towns—for Manchester may be taken as a fair example—is far from perfect, the closeness with which it is now watched is of good augury for the future. *But there is even now far too much apathy not only* among the poor but also among the well-to-do. Some time ago an attempt was made to establish a company in Manchester for the supply of pure milk, something after the plan of the Moelke Forsyning Company at Copenhagen, but it failed for want of adequate support. Mr. Sadler's apologia would be more effective if he did not go quite so near to denying that disease is communicated at all by milk and threaten the opposition of the farmers to any further increase of precautionary powers on the part of the authorities. The outbreak of sore-throat at Woking, for example, was distinctly traced by the medical officer to four cows with diseased udders. The truth is that though on many farms every care is taken to insure cleanliness there are a good number where the occupants are in a lower state of civilisation and where they are only clean when compelled to be. At a meeting to be held later Mr. Brittleshaw, the veterinary inspector of the corporation, will treat of the milk-supply from his point of view and his picture may perhaps differ considerably from Mr. Sadler's.

ST. BARTHOLOMEW'S HOSPITAL.

In The Lancet of Dec. 19th, p. 1741, we expressed a fear that the governors of this ancient institution had decided too late to ask for more land seeing that the Post Office was in the field against them. Since we wrote thus we learn that the Post Office has practically secured the whole of the remainder of the site of Christ's Hospital. The Post Office, however, will, we suppose, sell a portion of the site if asked to do so, and on Dec. 29th a meeting of the authorities of St. Bartholomew's Hospital was held at which it was determined that a deputation consisting of the treasurer and two almoners should approach the Postmaster-General with a view to obtain some of the recently purchased site. We hope that the deputation will go as men in no doubt of gaining their desires; and, moreover, that they will go prepared with a definite plan of the land which they require. It is no good to approach a Government department in a meek spirit nor under the idea that the asker *will not obtain his wish. The Postmaster-General* must be told that it is vital to the existence of the hospital that more land should be handed over to it on a site contiguous to that which it occupies at present, and we earnestly hope that the deputation will lose no chance of impressing this fact upon him. "Ask and it shall be given unto you" is as true now as it was 1900 years ago.

THE MEDICAL DIRECTORY FOR 1904.

THE 1904 issue of Messrs. J. and A. Churchill's Directory appeared with commendable promptitude in the last days of 1903. Among new features is a list of the members of the Central Midwives Board, while the index to the abstract of the principal laws affecting the medical profession has been arranged alphabetically. The total number of names for 1904 is 37,730, being an increase of 439 over the total for 1903. Of departmental increase the provincial English list shows 16,553 names, as against 16,422 in 1903, and the Naval, Military, and Indian Medical Services 3016 names, as against 2917 in 1903. The article which appeared in the Directory for 1903 under the heading of "Medical Staff College, R A M.C.," has its place taken by one dealing with the "Royal Army Medical College." The somewhat humorous entries in the useful classified list of books to which we drew attention last year have been modified by the omission of the possessive "s" after the authors' names and therefore in place of "Bland Sutton's Ovaries" or "Murray's Hare Lip" we read "Bland-Sutton—Ovaries" and "Murray—Hare Lip," which is without doubt an improvement. For the rest we can only say that the Directory is as complete and useful in every way as possible and the information contained in the introductory and other articles is kept well up to date.

HELLEBORE POISONING.

A CASE of poisoning by hellebore occurring at Sackville College, East Grinstead, was recently investigated by the East Sussex coroner. Evidence was given to show that John Davis, an aged inmate of the college, by the advice of a friend, prepared an ointment made from helleborus niger in order to allay an irritable skin disease. On the day of his death, being afflicted with pains in the stomach, Davis swallowed what he thought was a liquorice powder but in reality was the powder from which he had prepared his ointment. The two powders were kept in similar papers in a canister and Davis possessed only one eye, whilst the remaining one was affected. He discovered his mistake and proceeded to a druggist's shop in the town with the object of obtaining an emetic. The assistant, who later remarked that Davis's manner was as usual, advised him to consult a medical man at once, but whilst on the way home, and it is believed 20 minutes after he had swallowed the hellebore, he was attacked with great pain and was supported back to the college. Mustard and water proved unavailing as an emetic and all efforts to procure a medical man were fruitless. Davis remained conscious to within ten minutes of the end and died within two hours. The coroner remarked that, whilst admitting the poison was one comparatively unknown, no one appeared to be aware of the seriousness of the case and as Davis had called for a remedy it was the assistant's place to have given it to him. The druggist pointed out that the poison was not included under Schedule 1 or 2 but nevertheless he marked the packet "poison." Mr. James Harrison, M.R.C.S., L.R.C.P. Edin., warden at the college, gave his testimony. He did not see Davis until within seven or eight minutes of his death. In answer to the coroner Mr. Harrison stated that the effects of hellebore were that in the first place intense burning in the stomach ensued and then as absorption took place it naturally paralysed the nerve centre governing the heart, resulting, as in the present instance, in heart failure. Olive oil could be given as an emetic, but at present no antidote was known. A teaspoonful was sufficient to cause the death of six men. The coroner remarked that there was comparatively little known of the poison and the jury returned a verdict of "Death from misadventure." Cases of poisoning by hellebore are undoubtedly rare. The symptoms are very similar to those produced by veratrum and the two poisons may easily be mistaken for one another. Hellebore is strongly irritant to the mucous membranes and has an action on the heart resembling that of digitalis and it also acts on the nervous system. Hence, in overdoses it produces nausea, vomiting, salivation, and diarrhœa. The primary stimulating action upon the motor centres and the heart may not appear and the general depression will then be very marked. The heart's action becomes rapid and feeble and death from syncope is likely to occur. A case of poisoning by hellebore with recovery was recorded in THE LANCET, vol. ii., 1856, p. 100.

DISSEMINATED SCLEROSIS AND ITS ASSOCIATION WITH DEMENTIA.

DISSEMINATED sclerosis of the central nervous system is generally accompanied by slight mental changes. In the larger number of cases these psychical alterations are insignificant and play a minor rôle in the list of symptoms. They may be summed up briefly as follows: mental dulness and apathy varied by mild states of exaltation or melancholic depression of an ephemeral character. Another group of cases with the somatic symptoms of disseminated sclerosis is characterised by a preponderance of the mental symptoms which appear early in the course of the disease, are of unusual severity, and terminate in complete dementia. An account of this latter affection, which seems to have affinities with general paralysis of the insane, is published in the *American Journal of the Medical Sciences* for December by Dr. J. Ramsay Hunt, neurologist to the Cornell University Medical School. The group is represented pathologically by two subdivisions: (1) an extreme development of the sclerotic process in the grey and white matter of the brain (cerebral type of disseminated sclerosis); and (2) a mixed or combined form in which symptoms of multiple sclerosis and general paralysis coexist. Both forms, says Dr. Hunt, are rare, seven cases being recorded in literature to which Dr. Hunt adds an eighth which is as follows. The patient was a woman, aged 53 years, the mother of seven children. There were no miscarriages or evidences of syphilis. Her symptoms began four years previously with progressive weakness in the legs and slight defect of memory. These symptoms grew more marked and on admission to hospital there was marked spastic ataxia of gait with considerable mental enfeeblement. The upper limbs also exhibited ataxia and weakness, the speech was stammering and syllabic, the facial expression was one of stupid hilarity, and there were occasional impulsive attacks of laughter. Ophthalmoscopic examination showed the presence of double optic neuritis passing into atrophy. The patient complained of occipital tenderness and pains in the limbs. Paræsthesiæ ("numbness and tingling") were present in the extremities. Nystagmus was present but the pupils, though small, reacted normally to light and accommodation. The knee-jerks were increased on both sides but the tendon reflexes of the upper extremities were wanting. The sphincters acted normally. Occasionally involuntary ataxic movements of the arms and head occurred. The lower extremities were usually held in a state of semiflexion. The patient's physical condition gradually grew worse and she died at the end of four years' residence in hospital. The necropsy revealed the following conditions. The brain substance was somewhat atrophied and there was excess of cerebro-spinal fluid. The ventricles were enlarged and the ependyma was granular. Yellowish plaques of sclerosis sharply defined were found scattered throughout the cerebral and cerebellar hemispheres, involving both white and grey matter. Similar plaques were observed in the pons and medulla. The nerve cells of the cortex were extensively atrophied and the neuroglia was increased. In many parts the leptomeninges were thickened and infiltrated with round cells. The cortical arteries were thickened and the perivascular and pericellular spaces dilated and beset with pigment cells and fat granules. By Weigert's method a considerable loss of the radiating and association fibres of the cortex was demonstrated in the frontal, temporal, and occipital lobes. In these areas the tangential fibres were absent. Although the symptoms of disseminated sclerosis were not apparent until the forty-ninth year the cerebro-spinal distribution of the lesions, says Dr. Hunt, and the pathological appearances were identical with the juvenile form of sclerosis, "while the extent, character, and severity of the cortical degenerative process would correspond only to that observed in general paralysis of the insane." The diagnostic difficulties encountered in such cases are considerable. Nystagmus, scanning speech, and intention tremor when typically present will leave no room for doubt as to the presence of disseminated sclerosis, but if epileptiform or apoplectiform attacks occur and there is marked dulness of mind the diagnosis is difficult. The Argyll-Robertson pupil if present will indicate general paralysis, as it is very rare (occurring only in 1 per cent. of cases) in sclerosis. In all the cases personally observed or collected, says Dr. Hunt, a hereditary taint was traceable, with evidences of a defective nervous system in early life (imbecility, weak-mindedness, and in one case epilepsy).

THE POISONOUS CONSTITUENT OF TOBACCO SMOKE.

The gaseous products of the incomplete combustion of tobacco, whether it be smoked in the pipe, the cigarette, or the cigar, are so complex that the question—to which constituent are the toxic effects of tobacco smoking precisely due—remains unanswered. Of course, it is well known that nicotine is a powerfully poisonous constituent of tobacco leaf but it is *by no means certain that the alkaloid* reaches the system by way of the smoke in sufficient quantity to act seriously as a poison. To begin with, the amount of nicotine in tobacco is very small—and there is reason for believing that the quantity given in previous analyses has been considerably over-represented—moreover, though a volatile poison, nicotine does not occur in the free state in tobacco but as an organic salt which is not volatile and which probably breaks up readily on combustion. It is doubtful whether a seventh part of the total nicotine in the tobacco reaches the mouth of the smoker and some investigators deny that any nicotine occurs in tobacco smoke at all. But assuming that nicotine is the toxic constituent of smoke the quantity must be quite minute since in most mild tobaccos the proportion is rarely over 1 per cent. On the other hand, the incomplete combustion of tobacco gives rise to the formation of aromatic compounds, oils, bases, amines, and gases, some of which are undoubtedly poisons and these are obviously produced in a far larger amount compared with the quantity of nicotine in tobacco. In this connexion too little attention seems to us to have been paid to the relatively large quantity of the poisonous gas—carbon monoxide—in tobacco smoke. When the insidious nature of this gas is considered its absorption in the system, which must be very rapid when inhalation is practised, would sufficiently explain the train of poisonous symptoms which excessive smoking is apt to set up. In some particulars the physiological action of nicotine and carbon monoxide is similar. The dizziness and stupor, the trembling of the limbs and the hands, the disturbance of the nerve centres and of the circulation, palpitation on a slight effort, and the feeble pulse may be the indications of either carbon monoxide or nicotine poisoning. But since one ounce of tobacco gives no less than one-fifth of a pint of pure carbon monoxide gas when smoked in the form of cigarettes—and probably as much or more in the form of cigars or in pipes—it is not improbable that to a very large extent these symptoms are due to the carbon monoxide. We have recently tried the following instructive experiment which bears upon this point. Two or three mouthfuls of tobacco smoke from a cigarette were shaken up with a few drops of blood diluted with water in a bottle. Almost immediately the blood assumed the pink colour characteristic of blood containing this gas, and further observations with the spectroscope confirmed the presence in the blood of carbon monoxide. Similarly a few mouthfuls of smoke from a pipe and a cigar were tried and the results were even more marked. In this experiment we have some explanation in particular of the evil effects of cigarette smoking, for it is chiefly cigarette smoke that is inhaled—an indulgence by which the poisonous carbon monoxide is introduced directly into the blood. This effect of tobacco smoke upon the blood appears to us to be of considerable significance.

THE NEED FOR CLASSIFICATION OF PAUPERS.

On several occasions we have called attention to the necessity for improved classification of the inmates of workhouses and have shown how hardly the present system presses upon that small *percentage of the poor whose misfortunes are not* attributable to their own evil courses. The abhorrence with which respectable paupers regard the institutions professedly designed to minister to their wants is well known and has unfortunately only too substantial a foundation. An article in the December number of the *Nineteenth Century* by Edith Sellers, entitled "Shifting Scenes in Rural Workhouses," fully bears out the contentions maintained in these pages. We select the following examples from those given as illustrations of the abuses still existing. In one workhouse were found, all occupying the same living room and dormitory, 12 men, of whom two were murderers who had served respectively 20 and five years' penal servitude for their crimes, while another was a repulsive lunatic. Another male ward elsewhere contained 13 men, some of them ill but doing their best to get well as soon as possible so that they might escape from the unpleasant propinquity of the two idiots and the dangerous lunatic with bullying tendencies whose society was thrust upon them. The women were in similar evil case. At one small workhouse there were but two, of whom one was imbecile, so that the other found little companionship or sympathy of a desirable kind. The women's ward at another place was terrorised by "a harridan of the worst sort," known as "the Tigress," whose vagaries neither the officials nor the magistrates could or would control. At yet a third workhouse the family party consisted of two imbeciles, two feeble-minded persons, one vicious woman, and one unhappy old lady who, to the detriment of her peace of mind, was none of these things. With scenes like these before their eyes is it any wonder that to the deserving poor the workhouse is an accursed place? For the more striking features of the picture the various boards of guardians and their officials are in great measure responsible. It is an abuse of the powers given under Section 24 of the Lunacy Act, 1890, that lunatics of the class described should be detained in a workhouse. But even where the provisions of the Act are adhered to there remains much to be done. After eliminating those paupers whose abnormality in the way of vice or mental disorder is sufficiently marked to justify their detention in prisons or lunatic asylums, there remain other well-defined groups whose deserts differ widely although under the present arrangement all share alike in the charity publicly dispensed. An essential condition of any measure of reform is therefore suitable classification. In the larger unions of London and the provinces something is done in this direction by the removal of children and imbeciles to special homes or asylums, the provision of wards for lock cases, the appointment of male nurses to deal with the more ruffianly of the sick, and so on; but where the total number of paupers is small even this degree of separation is impracticable. There should be available for the poor of any district at least one institution between the workhouse on the one hand and the prison or lunatic asylum on the other, and in country places this could only be managed by a fusion of parishes and by using the existing buildings for distinct classes of cases.

SUBSTITUTION UNMASKED BY THE ROMAN LETTER "M."

THERE is a curious provision in the Bread Acts of 1822 and 1836 which are still in force to the effect that "every person who shall make for sale, or sell or expose for sale, any bread made wholly or partially of peas or beans or potatoes, or of any sort of corn or grain other than wheat, shall cause all such bread to be marked with a large Roman 'M.'" It would thus appear that the baker who chooses to put potatoes in his bread could escape the charge of adulteration by marking the loaf with this letter in the manner described, and it would be well occasionally to examine all loaves for this imprint, for it might very easily be unobserved or, if there, might be taken to mean something quite different. The plan seems to us to offer some advantages to the public if they were aware of it and the Roman "M" might be of real help in suppressing the very prevalent fraud of substitution. Thus, if it could be made compulsory to print a Roman "M" on a bottle of whisky which is not all malt, or on a bottle of brandy which is not all grape spirit, or on a fabric which is not all linen, and so forth, the public would know what they were getting and much of the deceit at present practised would be brought to light. The vendors of substitutes could not logically raise any objection to this process because they invariably argue that the substitute is better for the health and comfort of the buyer than is the genuine article.

FIRST FRENCH CONGRESS OF CLIMATOTHERAPY AND HYGIENE OF TOWNS.

A CONGRESS under this complicated name will be held at Nice during Easter, from April 4th to 9th, 1904, under the presidency of Professor Chantemesse. Among the vice-presidents are Professor Renaut (Lyons), Professor Grasset (Montpellier), Professor Calmette (Lille), and Dr. Balestre (Nice). The discussions will bear on the following five questions: (1) the climate of the French Mediterranean coast; (2) adaptation of the individual to climate; (3) influence of the French Mediterranean coast climate on tuberculosis and tuberculous patients; (4) the influence of climate on the French Mediterranean coast on rheumatism and on those subject to rheumatism; and (5) disinfection of towns. The members of the executive committee for England are Dr. G. H. Brandt (Nice), Dr. H. J. Johnston Lavis (Beaulieu), Dr. J. A. Macdougall (Cannes), Dr. R. Price Mitchell (Monte Carlo), and Dr. Stanley M. Rendall (Mentone). Great travelling facilities in France and abroad will be granted to members of the Congress and their families. The hotel prices at Nice will be reduced in their favour and may be ascertained beforehand. Applications for membership should be sent to Dr. Bonnal, treasurer, 19, Boulevard Victor-Hugo, Nice (Alpes-Maritimes). Dr. Hérard de Bessé, secretary-general of the Congress, Beaulieu-sur-Mer, will be happy to give all further information.

THE REGIUS PROFESSORSHIP OF MEDICINE AT OXFORD.

IN THE LANCET of Dec. 26th, 1903, p. 1828, we announced the resignation of Sir John Burdon Sanderson as Regius Professor of Medicine at the University of Oxford. The appointment to this office is, as its name shows, in the hands of the Crown, and the University has therefore no *locus standi* in the matter. But courtesy would suggest that the opinion of the University should at least be sought and it has come to our knowledge that a name has already been submitted to the Vice-Chancellor and transmitted by him to the Prime Minister for succession to the post without any of the Oxford graduates in medicine having been given a chance of recording their opinion regarding the successor of the late Regius Professor or of intimating their wishes in the matter. As we have already said, the new Regius Professor should be one not merely with a grasp of modern medicine but also one who can take a broad and statesmanlike view of the principles and influence of the medical sciences. There are at least four or five Oxford graduates who would be willing and able to take the post and who, moreover, are men of the type which we have mentioned. But none of these has been asked and an attempt has evidently been made to rush the appointment through in what we think is a very undesirable manner. It is to be hoped that the Prime Minister will at least hold his hand until he has been able to learn the opinion of the Oxford graduates upon the matter. The Regius Professorship of Medicine is a post of dignity and one of importance to the University. Its holder should be a statesman-like man as well as a teacher and undue hurry in the appointing of the professor is most strongly to be deprecated.

GONORRHŒAL PYÆMIA IN INFANTS.

IN a recent number of the *Medical Record* Dr. R. B. Kimball calls attention to a form of gonorrhœal pyæmia not previously recognised. It appears that in American institutions in which infants and elder children are associated gonorrhœal vulvo-vaginitis is prevalent. The infection once introduced spread with great rapidity, attacking practically all the females and unless precautions are taken some of the males also. During one year 600 patients were admitted to the Babies' Hospital of New York among whom occurred 70 cases of gonorrhœal vulvo-vaginitis and ten of arthritis. In these cases there was only one case of ophthalmia. A large proportion of the vaginitis was acquired in the hospital. To check the outbreaks the most elaborate precautions were necessary. Nothing but complete isolation prevented the spread of the disease. In eight of the ten cases of gonorrhœal arthritis (pyæmia) no local source of the disease could be found. No similar cases appear to have been recorded. The following case is an example. A girl, aged three months, was admitted on June 18th, 1902, for acute entero-colitis. Until the 28th there were only symptoms of mild entero-colitis. Then the temperature rose to 105° F. and on the following day the left knee and hand were swollen, red, hot, and painful. On July 1st both knees and both hands were affected. On the 2nd the ankles were involved. On the 5th fluctuation was obtained over the right ankle and aspiration yielded a drop of pus. General œdema set in and death occurred on the 12th. There was never any vaginal discharge. At the necropsy pus was found in the right shoulder-joint, the tissues about the left shoulder-joint, and the tissues about the wrists (not the joints). The pus contained gonococci. The identification of the organism was confirmed by Professor Welch of the Johns Hopkins Hospital. In the eight cases all the patients were infants under the age of three months and, strange to say, seven were males. On the other hand, of over 70 females suffering from vaginitis only one had arthritis. In six cases there were purulent polyarthritis, peri-arthritis, and myositis. In two cases only one joint (the knee) was involved. The ankles and wrists were the joints most frequently affected In two cases the temporo-maxillary joints were involved and in three the toe- or finger-joints. The treatment consisted of aspiration or arthrotomy with application of wet dressings. The incisions healed and the joints were restored to normal with remarkable rapidity. No history of gonorrhœa in the parents or of ophthalmia neonatorum could be obtained. Six of the eight cases were fatal and at the time of the report the recovery of the two survivors was doubtful. In three cases necropsies were obtained. Arthritis, purulent infiltration of the muscles about the joints, and broncho pneumonia were found. In one case there were laryngeal abscesses and the pus as well as the laryngeal mucus yielded biscuit-shaped diplococci not retaining Gram's stain. In three cases a form of stomatitis resembling thrush was present and in one case intracellular diplococci not retaining Gram's stain were found in the scrapings from the mouth, but the organism could not be isolated and proved to be the gonococcus. Cases of gonorrhœal stomatitis in the newly born have been previously described. Dr. Kimball suggests that during cleansing of the mouth infection may have taken place from the nurse's hands and that the resulting stomatitis was the source of the pyæmia.

THE medical officer of health of the Cape Colony reports that for the week ending Dec. 5th, 1903, no cases of plague were notified in the Colony. Plague infected rats continued to be found at various places in the Colony, but of 400 rats which were examined in the Cape Town and harbour board area during the week none was affected with plague.

Dr. Arthur Newsholme will deliver the inaugural address in connexion with the post-graduate lectures and demonstrations at the Mount Vernon Hospital for Consumption and Diseases of the Chest, 7, Fitzroy-square, W., on Thursday, Jan 7th, at 5 P.M. The subject of Dr. Newsholme's address will be Public Preventive Measures against Tuberculosis in Relation to the Medical Practitioner.

AT the next meeting of the Incorporated Society of Medical Officers of Health, to be held at 9, Adelphi-terrace, Strand, London, W.C., at 8 P.M., on Friday, Jan. 8th, Dr. J. Spottiswoode Cameron will open a discussion on Sophistication of Foods and important motions will be proposed. The meeting is open to public analysts and those interested in the subject.

THE Royal Commission on Sewage Disposal at its meeting on Dec. 22nd settled its report on the contamination of shell fish by sewage. The report will be published in a few days.

THE LONDON SCHOOL OF TROPICAL MEDICINE.—Of the students of the above school who presented themselves for the examination at the end of the October-December, 1903, session the following have passed: A. E Horn (Colonial Service), A. H. Barclay (Foreign Office), G. Wilson, W. J. Radford (Foreign Office), D Cowin (Colonial Service), J. E Mitchell, S G. Ranaday, C. H. Allan (Colonial Service), J. T. Cartaya, F. A. Baldwin (Colonial Service), T. F. G. Mayer (Colonial Service), F. C. Sutherland, and Guy Ruata.

THE WORKING OF THE INEBRIATES ACTS.

THE report of Dr. R. Welsh Branthwaite, H.M. Inspector under the Inebriates Acts, which has recently been issued, contains even more information than its predecessors and either with or without them might usefully be studied by every county and borough councillor and magistrate in the kingdom. Indeed, it is difficult to see how, without the careful consideration by all concerned of the points to which Dr. Branthwaite calls attention in his comments upon the statistics which he presents, thoroughly efficient working of these important Acts can ever be obtained. The progress which he shows is satisfactory as far as it goes, but some of the defects which he also criticises appear to be unnecessary and capable of remedy. Those who consider the question of the responsibility of the community for the care of the habitual inebriate should, in order to avoid confusion, bear carefully in mind the distinct forms of establishment provided by law for this purpose. The retreat established under the Inebriates Act, 1879, is for the reception of habitual drunkards voluntarily submitting themselves to its restraint. The State Inebriate Reformatory instituted under the Inebriates Act, 1898, is primarily for habitual drunkards convicted on indictment of offences punishable with imprisonment under Section 1 of that Act. As its name implies it is a State institution, provided and maintained at the expense of the Treasury. The Certified Inebriate Reformatory, also a creation of the Act of 1898, may be instituted by county or borough councils or private individuals and is primarily for the reception of inebriates convicted under Section 2 of the Inebriates Act, 1898, of minor offences connected with drunkenness four times within 12 months Persons originally confined in State Inebriate Reformatories may be removed to Certified Inebriate Reformatories and *vice versâ*, and in practice this transference has been frequently found desirable, as the person who has been convicted of an indictable offence committed through drink often proves more tractable than the person who has become liable under Section 2 and so may be advantageously treated in the less rigorously disciplined surroundings provided by voluntary effort, whereas the comparatively harmless soaker who cannot be committed to any but a certified reformatory sometimes proves not amenable to the restraints that are there available. An important element of weakness in the administration of the Act of 1898 to which Dr Branthwaite refers lies in the fact that it does not cover the whole ground of habitual inebriety coming before courts of law owing to the voluntary element introduced into the working of certified reformatories Acceptance into these is dependent upon whether the managers of the institution are willing to receive the inebriate offered to them. A proportion of those convicted under Section 2 may fairly be described as cases hopeless of reform, at all events within the period for which detention is ordered. No case, perhaps, should be pronounced with authority to be beyond possibility of improvement, but persons of the type of Jane Cakebread and Tottie Fay, whose sad cases contributed largely to the institution of the certified reformatory, are precisely those whom managers of these institutions are likely to reject. This operates in two ways; the unfortunate inebriate after a short time in gaol is left at large to do mischief to himself and to the community and the magistrate who finds a drunkard thrown back upon his hands is discouraged from committing other inebriates to the reformatory. He may even misunderstand the causes at work, denounce the Act as inefficient, and delay its operation in the district where he presides. Dr Branthwaite makes out a strong case for the admission even of the worst cases to the institutions provided by local authorities for the benefit of their localities, although to do so would necessitate taking charge of

encourages the mag

future for himself as to which case is capable of beneficial treatment and which is not, a matter as to which he cannot possibly be in a position to form a correct opinion.

We have suggested above that the Blue-book containing Dr. Branthwaite's report might usefully be read by all county and borough councillors and by all magistrates, because upon the provision of accommodation for inebriates by the former and upon a proper appreciation of the work done by reformatories on the part of the latter the successful working of the Act of 1898 entirely depends. With regard to the provision of accommodation we have suggested that the reception of all cases, if possible, is desirable in the public interest. Apart, however, from questions of discrimination we find by the report for 1902 that at the end of that year a number of counties and boroughs had entirely failed to avail themselves of the Act or had done so to a very slight degree only. A study of Dr. Branthwaite's figures will show this in detail. It may be summarised by saying that on June 30th, 1903, out of 495 inmates of inebriate reformatories 259, or more than 50 per cent of the whole, came from London and the metropolitan district. Lancashire added approximately another 25 per cent. and the remaining 25 per cent. were made up by the whole of the rest of England and Wales.

The contribution of Wales at the end of 1902 amounted to 12 only, of whom 11 came from Glamorganshire and one from Carnarvonshire. We are not aware that any feature of universal sobriety entitles the rest of the principality to dispense entirely with the assistance which the Act under consideration offers, and the same observation applies to Bedfordshire, Cambridgeshire, Cornwall, Derbyshire, Herefordshire, Huntingdonshire, Lincolnshire, Oxfordshire, Rutland, Suffolk, Westmorland, and Wiltshire, from none of which at the same date had any person been committed to an inebriate reformatory. Four more counties had made use of the Act in one instance only, one on two occasions only, and Cumberland and Leicestershire, while sufficiently aware of the Act to contribute four each to the total, had not found it desirable to exceed that number.

The failure to make use of the powers given lies partly at the door of local authorities who are, however, in many instances making efforts to obtain the best possible accommodation for the treatment of their inebriates. Counties and boroughs may contribute to the construction and maintenance of a certified reformatory or may arrange for the accommodation of inmates in such institutions by payment. The majority of the certified reformatories which came early into existence were to be found in the southern portion of England. The Lancashire reformatory at Langho was not completed at the time when the Blue-book before us was compiled and the Yorkshire reformatory, the plans of which are given, had been but recently commenced. The completion of these two should inspire the building of others besides setting free accommodation elsewhere.

In addition, however, to that of the local authority the goodwill of the occupants of the bench is necessary. Magistrates may have been discouraged by the failure to obtain treatment which has followed their committal of individual cases. Want of accommodation and the unwillingness to treat apparently hopeless cases have contributed to this, but magistrates must be reminded with reference to the latter cause that the hopeless cases of the present day are due to the want of power to deal with cases not yet irremediable in the past. Reformatories are primarily for reform and must be used for those who are not too far gone to be treated if the treatment is to be effectual. Any tendency to give the drunkard "one more chance" to reform himself when he is qualified for compulsory treatment is false kindness which may result in his final ruin, and any attempt to minimise his sentence is no less cruel to him. The reformatory cannot do him much good during a term of a few months only. If it proves effective in less than the period for which his committal has taken place those who manage it have power to allow him out on licence, and considerable care is exercised to render such period of probation a useful part of the treatment.

It is possible, moreover, that the judges, who at assizes have the opportunity of calling marked attention to the Inebriates Act of 1898, do not always exercise their influence with regard to it to their fullest extent. Mr. Justice Grantham by his observations at the last Durham assizes and by the controversy in which he has involved himself with the licensed victuallers has drawn a good deal of public notice to the connexion between drunkenness and crime. He has, however, thrown upon the publicans a very large proportion of the blame which in many cases may be deserved and has not, so far as we are aware, contributed in any marked degree to the effectual working of the Act, either by reference to the powers which it gives or by criticising, with the aid of his experience, its merits and demerits. The man or woman whom drink converts into a violent criminal is a person whom most publicans would gladly be rid of, but it is for judges and magistrates to place such inebriates under salutary restraint.

Section 1 provides as follows:—

> Where a person is convicted on indictment of an offence punishable with imprisonment or penal servitude, if the court is satisfied from the *evidence that the offence was committed* under the influence of drink or that drunkenness was a contributing cause of the offence, and the offender admits that he is, or is found by the jury to be, an habitual drunkard, the court may in addition to, or in substitution for, any other sentence order that he be detained for a term not exceeding three years in any State reformatory or in any certified inebriate reformatory the managers of which are willing to receive him.

The rest of the section deals with the procedure to be adopted should the prisoner refuse to admit his habitual drunkenness so as to necessitate evidence being heard upon the subject. Up to the end of 1902 there had been no State reformatory available and so the figures given in Dr. Branthwaite's report refer only to certified reformatories willing to receive the inebriate convicted on indictment. This accounts in a measure for the number of committals to reformatories being small, coupled as it is with the necessity which still remains for conviction upon indictment at quarter sessions or assizes. It is, however, to the nature of the offences which have led to committals to reformatories under this section that Dr. Branthwaite points in support of his suggestion that insufficient use has been made of it. There have been in four years 96 such committals, of which no less than 78 have followed convictions under the Cruelty to Children Act. This is equivalent to saying that but for the efforts of the National Society for the Prevention of Cruelty to Children to save children from neglect and ill-treatment (not to reform drunkards) this useful section would have been almost inoperative. This state of affairs must to some extent be due to the apathy of judges and magistrates, although there is one cause which no doubt prevents it from being put into effect in some otherwise suitable instances. To this Dr. Branthwaite does not appear to give weight. It is the necessity, which reference to the section cited will show, of proving by evidence that the convicted person is a habitual drunkard in cases where he denies it. In some instances this may be easy—as, for example, where frequent convictions at a police court for offences connected with drunkenness have preceded the conviction on indictment. On the other hand, the convicted person may not be a "habitual" drunkard at all, or he may be one, and yet there may be considerable difficulty in proving him to be such to the satisfaction of the jury. Again, apart from lack of evidence, juries have their prejudices; there may be persons upon any jury who for various reasons would rather see the convicted person punished without reference to the Inebriates Act. It is, however, for judges and chairmen of quarter sessions primarily to render this section effective if the community and the victims of inebriety are to reap the full advantage of it. Imprisonment may precede the term in a reformatory as the section shows.

The statistics which relate to the use of retreats under the Act of 1879 by persons consenting to be treated in them are not very encouraging, although they show some increase in the number of those admitted. There were 552 received into retreats in 1902, as against 433 in 1901 and 422 in 1900. In 1899 there were 437. The increase for 1902 is accompanied by a curious rise in the number of females admitted. This rose to 305, as against 186 in the previous year. As a rule there has been a preponderance of women among those committed to reformatories and a preponderance of men among those voluntarily consigning themselves to retreats, and the new condition may be merely temporary and accidental. That the use made of the power of self-committal to restraint of this kind should be small compared with the number of habitual drunkards is not surprising when we consider that the drunkard in his soberest moments is not a person whose good resolutions are likely to last long and no doubt they have often time to weaken before the formalities imposed by the Act are complied with. At present the inebriate in England cannot as such be compelled to accept treatment, as he can in some countries. To the possibility of providing for this Dr. Branthwaite refers, as well as to the other cause which has militated against the success of the retreat. This is simply the lack of funds. The poor patient finds little accommodation provided for him and the destitute inebriate finds none unless charity will come to his aid. These persons are, in fact, in a worse position than if drunkenness led them to offend against the law. On the whole the Blue-book shows regular if somewhat slow progress in the work of the two classes of reformatory and of retreats, and the perusal of its contents may be recommended to those who can accelerate a development which is much to be desired.

POST-GRADUATE WORK ABROAD.

VIII. CHICAGO.[1]

BY J. B. MURPHY, A.M., M.D.,
PROFESSOR OF SURGERY IN THE NORTH-WESTERN UNIVERSITY SCHOOL, CHICAGO; SURGEON-IN-CHIEF, MERCY HOSPITAL, CHICAGO, ETC.

THE conditions underlying post-graduate study in Chicago are entirely different from those obtaining in Europe, and especially in Berlin, Vienna, or Paris. The great majority of hospitals are not under government or municipal control and we have no "faculty of medicine" in a public official sense. Neither have we bodies like the "Assistance Publique" whose ticket entitles the holder to admission to the various hospitals under its control. The place of these two bodies is largely taken by the post-graduate schools, of which more anon. Chicago, like Gaul, is divided into three parts, separated by the Chicago river and its branches. Each of these has a post-graduate school, one or more medical colleges, and many hospitals.

The largest division—the west—has the so-called "medical centre" of Chicago, with the County Hospital for a nucleus. This institution is one of the largest general hospitals in the United States, having 1200 beds. The county morgue and the Detention Hospital for the Insane are on the same grounds. Clinics are held in the amphitheatre continuously throughout the day by various members of the attending staff but there is no bedside instruction. A ticket, good for one year, admitting the holder to all clinics and necropsies costs five dollars (one pound). Within a square or two are four medical colleges, a post-graduate school, and three hospitals, which are the Presbyterian Hospital, the West Side Hospital, and the Women's Hospital.

The south division has the new but very prosperous Chicago University. The medical schools and hospitals are again located close to each other but some miles nearer the city proper than the university. The principal hospitals are the Mercy Hospital, with 260 beds, the Wesley Hospital, with about half the number, and St Luke's Hospital. The north side has fewer hospitals and medical schools The most important of these are the Alexian Brothers' Hospital for men only (this is the best constructed and equipped hospital in Chicago and has 280 beds; all of the patients may be used for clinical purposes, though many of them are pay patients), St. Joseph's Hospital, and the Augustana Hospital.

A prospective seeker for post-graduate instruction could write to the secretaries of the various post-graduate schools for their annual announcements. Their addresses are as follows: west side, Dr. W. L. Noble, 819, West Harrison-street; south side, Dr. F. H. Martin, 2400, Dearborn-street; and north side, Dr. M. L. Harris, 176, East Chicago Avenue. After perusing the lists of faculties and weighing the advantages offered by each institution he will probably make a decision or possibly he may delay it until arriving in the city. The clerks at the schools are provided with lists of rooms, boarding houses, &c. The faculties of the schools are all connected with a hospital, sometimes with several, and schedules of the various operations and medical clinics for the day and the day following are displayed on the bulletin board. The time is pretty well occupied with the clinics in the schools and at the hospitals near by. However, most physicians find time for a course in some special line—operations on the cadaver, bacteriology, pathology, histology, and the like. As a general rule, tickets for two or three months stay at a post graduate school will cost from $75 to $100 (from 15 to 20 pounds); the special courses each cost from $10 to $25 (from two to five pounds), depending on the number of sessions, &c. Some reduction is generally made when a stay of two, three, or more months is made. No precise figures can be given for board or lodging, as individual tastes differ so much. The former in families will run from 15*s.* per week, the latter from 8*s.* to 10*s.*, including heat, light, and attendance There is no lack of opportunities for special work. For instance, in ophthalmology and otology the Illinois Eye and Ear Infirmary, which is maintained by the State, is located here and has a very large out-patient department in addition to the wards. Clinic tickets, good for one year, cost five dollars. There is also a private Eye, Ear, Nose, and Throat Hospital (Dr. J. R. Hoffman, secretary, 206, East Washington-street) which gives regular instruction in diseases of any or all of these organs. For laboratory work there are abundant facilities also. Arrangements may be made with the instructors in the schools or colleges to pursue any desired subject, the cost depending on the importance of the subject and the length of time necessary. The University of Chicago offers courses on every conceivable subject—advanced anatomy, pathology, bacteriology, anatomy of the eye and ear, neuro pathology, &c. These usually occupy one quarter (three months) of the university year and cost from $25 to $50 (from five to ten pounds) each.

For those interested in psychiatry the Detention Hospital affords a wide field. The Insane Court is held here every Thursday and all patients brought in since the previous session are examined. If committed to the asylums they are generally sent to the county one at Dunning, some 15 miles out in the suburbs (fare, six cents) The infirmary, or poor house, is located here also, the two institutions combined having a capacity of some 2500. The nearest State asylums are at Elgin, 25 miles west (fare $1, or 4*s*), with a capacity of 1500, and Kankakee, 50 miles south (fare $1½, or 6*s*), with a capacity of 2500. As regards medical libraries, the Newberry Library on the north side (ten minutes' ride), while of recent origin, has some 20,000 volumes and about 200 current periodicals. Chicago has nothing to boast of in the way of pathological museums These are of slow growth and as the medical colleges were burned in the great fire or have been started since there is little but a nucleus as yet. In general museums the Field Columbian Museum (south, 30 minutes' ride), though less than a decade old, has a really wonderful collection of specimens in comparative anatomy, anthropology, zoology, &c. The Academy of Sciences (north, 20 minutes' ride) has a similar but smaller collection.

The various medical societies, surgical, gynæcological, &c., have been recently combined with the Chicago Medical Society and are now branches of it. The parent society and its branches have meetings once a week or more often. Little or no influence is exerted by the season of the year on the character of the work. The summer is never unduly hot for any length of time and the nights are generally cool owing to the lake breezes. Early in the spring—February and March—there is (as elsewhere) some raw, damp weather for a few days. For physicians desiring to spend a few days only in the various medical centres of the United States, combining business with pleasure and coming over, as the Hindoos say, "to smell the air," the presentation of a professional card will insure them courteous attention and admission to the clinics for the short time of their stay.

The advantages of Chicago post-graduate students are the accessibility of the different institutions. All distances were measured from the court house and the principal hospitals, colleges, &c, are within a radius of two miles in each direction. By a series of electric trams (fare five cents., or 2½*d.*) nearly every desired point can be reached within a square or so. The surgeons in Chicago rarely ever operate in private residences; all of their operations are made in the hospitals. Visiting physicians are admitted to the private operations The custom adds enormously to the opportunities for witnessing surgical work in Chicago.

Next, the hospitality of the Chicago people which, of course, includes the physicians The latter take especial pains to interest their visiting brethren and divide their stores of wisdom with them The enterprise which has made Chicago world-famed from a commercial standpoint extends to the medical fraternity also. Nowhere in the country do we find the doctors more harmonious, skilled, and progressive.

REVIEWS.

II.[1]

Case of Carotid Aneurism, successfully treated by tying the Artery above the Aneurismal Tumour. By JAMES WARDROP, Esq., Surgeon Extraordinary to the King. Part 1st of the 13th Vol. of the Medico-Chirurgical Transactions. Longman. London.

WHILE the *science of Medicine* may be said to revolve in a circle, and while it may be fairly questioned whether *the practice of Physic* be more or less useful to the human species than it was in the days of Galen and Hippocrates, the merest tyro has only to glance at the history of the *art of Surgery*, during the last half century, and be delighted, nay, fascinated, by its astonishing progress—its almost incredible improvement.

In connexion with the subject to be treated of, it may be added, that in no department of surgery is the triumph of genius and talent, of anatomy and pathology, more conspicuous than in that which relates to the history and the treatment of aneurism. Before the days of the immortal John Hunter, the nature of this disease was not well understood, and the means of cure often proved ineffectual. Some patients were cured spontaneously by an effort of Nature, some by the assistance of pressure, and many were left to the horrid fate of lingering out life under an impression that every moment might be their last; the parietes of an aneurismal sac, or the common teguments, often being the only barrier between existence and eternity. Of those persons, who submitted to the *old operation*, a great many died, and many had very tedious cures. In this state of anxiety, uncertainty, and imperfection, with respect to the proper treatment of aneurism, Hunter arose, like the morning sun, and dispelled the shades of darkness. His profound knowledge of the animal economy enabled him to form a rational theory, upon which he not only grafted a new operation—the celebrated operation for popliteal aneurism,—but he also laid the basis of the astonishing operations of his successors. Could our ancestors start from their graves, with Hunter in the front rank, what would be their surprise—their amazement, on beholding the surgeons of these days, not only successfully tying the femoral, the humeral, and the external and internal carotid arteries, but absolutely putting ligatures on the common iliac, the external iliac, the internal iliac, the common carotid, and the subclavian arteries?—Would they believe their own eyes when they remarked one dexterous operator tying the *arteria innominata*, and another still more hardy, as the *ne plus ultra* of our art, ripping up the abdomen, turning aside the intestines, and absolutely carrying a ligature around the great trunk of nourishment of the whole animal system, *the aorta? ! !*

Since Hunter's days the pathology of aneurism has been fully developed, especially by Scarpa and Burns. The mode in which nature arrests hæmorrhage, and the manner in which ligatures act upon tied arteries, have been completely investigated by Thompson, Jones, and many others. In consequence of a combinaion of the improvements of the whole of the *faculty of surgery*, the above mentioned series of new operations has been performed; every artery of the system has been included in a ligature.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8581 births and 5159 deaths were registered during the week ending Dec. 19th The annual rate of mortality in these towns, which had been 17·6, 18·6, and 19 2 per 1000 in the three preceding weeks, declined again to 17·8 per 1000. In London the death-rate was 16·8 per 1000, while it averaged 18·3 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 8·2 in King's Norton, 9·0 in East Ham, 9·1 in Bournemouth, 9·7 in Barrow-in-Furness 10·3 in Grimsby, 10·6 in Hornsey, and 11 1 in Burton-on-Trent; the highest rates were 23·1 in Hanley, 23·2 in Walsall, 23·5 in Wigan, 23·6 in Warrington, 24·0 in Swansea, 24·1 in Stockton-on-Tees, 24·4 in Gateshead 34·5 in York, and 36·0 in Preston. The 5159 deaths in these towns included 423 which were referred to the principal infectious diseases, against 430, 402, and 42 in the three preceding weeks; of these 423 deaths, 134 resulted from measles, 113 from whooping-cough, 71 from diarrhœa, 43 from diphtheria, 35 from "fever" (principally enteric), 24 from scarlet fever, and three from small-pox. In Croydon, Hornsey, Tottenham, Norwich, Derby, Halifax, South Shields, Newcastle on-Tyne, and in ten other smaller towns no death from any of the principal infectious diseases was registered; while among the other towns they caused the highest death-rates in Willesden, Wigan, Warrington, Bury, Preston, Rotherham, York, and Gateshead. The greatest proportional mortality from measles occurred in Willesden, West Ham, Ipswich, Aston Manor, Warrington, Bury, Preston, Rotherham, and York; from whooping-cough in Wolverhampton, Walsall, Liverpool, Wigan, Warrington, Rochdale, York, Gateshead, Merthyr Tydfil, and Swansea; and from diarrhœa in Walsall, Preston, Gateshead, Rhondda, and Merthyr Tydfil. The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns. Two fatal cases of small-pox were registered in Gateshead and one in Warrington, but not one in any other of the 76 large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 40, 35, and 32 at the end of the three preceding weeks, had further declined to 26 at the end of the week; six new cases were admitted during the week, against three, three, and two in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Dec. 19th, was 1654, against 1770, 1715, and 1717 on the three preceding Saturdays; 188 new cases were admitted during the week, against 157, 161, and 173 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 399, 358, and 417 in the three preceding weeks, declined again to 344, and were 45 below the number in the corresponding period of 1902 The causes of 56, or 1·1 per cent., of the deaths in the 76 large towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Leeds, Hull, Newcastle-on-Tyne, and in 49 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Wallasey, Liverpool, Bootle, Halifax, Sheffield, and South Shields.

During the week ending Saturday last, Dec. 26th, 6251 births and 4464 deaths were registered in 76 of the largest English towns. The annual rate of mortality in these towns, which had been 18 6, 19 2, and 17·8 per 1000 in the three preceding weeks, further declined last week to 15·4 per 1000. The rates in the several towns ranged from 7·1 in Barrow-in-Furness. 7·3 in Leyton. 7·6 in East Ham, 7 8 in Walthamstow, 7·9 in Hastings, 8·0 in Hornsey, 8·9 in Smethwick, and 9·0 in Tottenham and in Reading, to 21·1 in Great Yarmouth, 21·5 in Bradford, 22·6 in Merthyr Tydfil, 23·4 in Stockport, 24·1 in Stockton-on-Tees, 24·6 in Preston, 26·7 in Warrington, 29·4 in Wigan, and 30·6 in York. In London the death-rate was 13·6 per 1000, while it averaged 16·3 per 1000 in the 75 other large towns. The 4464 deaths from all causes in the 76 towns last week included 388 which were referred to the principal infectious diseases, against 401, 422, and 423 in the three preceding weeks; of these 388 deaths 130 resulted from measles, 111 from whooping-cough, 47 from diarrhœa, 38 from diphtheria, 32 from "fever" (principally enteric), 25 from scarlet fever, and five from small-pox. In Croydon, Hornsey, Walthamstow, Brighton, Reading, Hull, South Shields, and eight other small towns no death from any of the principal infectious diseases was registered; while among the other towns they caused the highest death-rates in Willesden, West Bromwich, Warrington, Preston, Rotherham, Gateshead, and Swansea. Measles was proportionally most fatal in Willesden, Great Yarmouth, West Bromwich, Warrington, Preston, Leeds, Rotherham, and Sunderland, diphtheria in Hanley, and whooping-cough in Leyton, Liverpool, Wigan,

---

[1] Only a portion of this Review has been transcribed.

Warrington, Stockton-on-Tees, Gateshead, and Swansea; the other principal infectious diseases caused no excessive mortality in any of the large towns. Three deaths from small-pox were registered in Warrington, one in London, and one in Tynemouth. The Metropolitan Asylums hospitals contained 27 small pox patients on Saturday last, Dec. 26th, against 35, 32, and 26 on the three preceding Saturdays; seven new cases were admitted during the week, against three, two, and six in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 1715, 1717, and 1654 at the end of the three preceding weeks, had further declined to 1617 at the end of last week; 142 new cases were admitted during the week, against 161, 173, and 188 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 358, 417, and 344 in the three preceding weeks, further declined last week to 271, and were 138 below the number in the corresponding period of last year. The causes of 54, or 1·2 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Bradford, Leeds, Newcastle-on-Tyne, and in 48 other smaller towns; the largest proportions of uncertified deaths were registered in Northampton, Liverpool, Bootle, Warrington, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·7, 20·0, and 22·4 per 1000 in the three preceding weeks, declined again to 21·0 per 1000 during the week ending Dec. 19th, but showed an excess of 3·2 per 1000 over the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·7 in Leith and 15·8 in Greenock, to 23·2 in Perth and 23·3 in Paisley. The 686 deaths in these towns included 33 which were referred to measles, ten to diarrhœa, nine to whooping-cough, three to diphtheria, two to small-pox, two to scarlet fever, and two to "fever." In all, 61 deaths resulted from these principal infectious diseases during the week, against 62, 53, and 73 in the three preceding weeks. These 61 deaths were equal to an annual rate of 1·9 per 1000, which was 0·4 per 1000 above the mean rate for the week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 17, 22, and 34 in the three preceding weeks, declined again to 33, of which 30 occurred in Glasgow and two in Edinburgh. The deaths from diarrhœa, which had been 22, 12 and 15, in the three preceding weeks, decreased again to ten, all of which were registered in Glasgow. The fatal cases of whooping-cough, which had been nine, seven, and 13 in the three preceding weeks, declined again to nine and included four in Glasgow and three in Aberdeen. The deaths from diphtheria, which had been five, four, and two in the three preceding weeks, rose again to three, of which two occurred in Edinburgh. The fatal cases of small-pox, of scarlet fever, and of "fever" were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 148, 138, and 192 in the three preceding weeks, declined again to 184, but were 14 in excess of the number in the corresponding period of 1902. The causes of 27, or nearly 4 per cent., of the deaths in these eight towns were not certified.

In eight of the principal Scotch towns the annual rate of mortality, which had been 20·0, 22·4, and 20·9 per 1000 in the three preceding weeks, declined to 20·8 per 1000 during the week ending Dec. 26th, but was 5·4 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·0 in Paisley and 13·7 in Leith to 23·3 in Greenock and 24·9 in Dundee. The 680 deaths in these towns last week included 25 from measles, 16 from whooping-cough, 16 from diarrhœa, four from small pox, four from scarlet fever, four from diphtheria, and four from "fever." In all, 73 deaths resulted from these principal infectious diseases last week, against 53, 73, and 61 in the three preceding weeks. These 73 deaths were equal to an annual rate of 2·3 per 1000, which was 1·0 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 22, 34, and 33 in the three preceding weeks, further declined last week to 25, of which 23 occurred in Glasgow. The deaths from whooping-cough, which had been seven, 13, and nine in the three preceding weeks, rose again to 16 last week, and included eight in Glasgow, five in Aberdeen, and two in Edinburgh. The fatal cases of diarrhœa, which had been 12, 15, and 10 in the three preceding weeks, increased last week to 16, of which 10 were registered in Glasgow. The deaths from small pox, which had been three, two, one, and two in the four preceding weeks, further rose to four last week, and all occurred in Glasgow. The fatal cases of scarlet fever, which had been one, six, and two in the three preceding weeks, rose again last week to four, of which two were registered in Glasgow. The deaths from diphtheria, which had been four, two, and three in the three preceding weeks, further rose to four last week, and included two in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been two in each of the two preceding weeks, increased last week to four, of which two occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 138, 192, and 184 in the three preceding weeks, further declined last week to 180, and were 13 below the number in the corresponding period of last year. The causes of 26, or nearly 4 per cent., of the deaths registered in these towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·8, 27·5, and 24·6 per 1000 in the three preceding weeks, rose again to 25·6 per 1000 during the week ending Dec 19th. During the previous four weeks the death-rate averaged 25·6 per 1000, the rate during the same period being 17·7 both in London and in Edinburgh. The 186 deaths of persons belonging to Dublin registered during the week under notice were seven in excess of the number in the preceding week and included ten which were referred to the principal infectious diseases, against 11, 13 and 11 in the three preceding weeks; of these, four resulted from whooping-cough, two from scarlet fever, two from diphtheria, one from "fever," and one from diarrhœa, but not any from small pox or from measles. These ten deaths were equal to an annual rate of 1·4 per 1000, the death-rates for the week from the principal infectious diseases being 1·3 in London and 0·8 in Edinburgh. The fatal cases of whooping-cough, which had been three, five, and seven in the three preceding weeks, declined again to four. The 186 deaths of persons in Dublin during the week included 33 among children under one year of age and 63 among persons aged 60 years and upwards; the deaths of infants exactly corresponded with the number in the preceding week, while those of elderly persons showed a slight excess. One death from violence and seven inquest cases were registered; and 64, or more than a third, of the deaths occurred in *public institutions*. The causes of nine, or nearly 5 per cent., of the deaths registered in Dublin last week were not certified.

The death-rate in Dublin, which had been 27·5, 24·6, and 25·6 per 1000 in the three preceding weeks, declined again to 19·9 per 1000 during the week ending Dec. 26th. During the past four weeks the death-rate has averaged 24·4 per 1000, the rates during the same period being 16·8 in London and 17·1 in Edinburgh. The 145 deaths of persons belonging to Dublin, registered during the week under notice, showed a decline of 41 from the number in the preceding week, and included seven which were referred to the principal infectious diseases, against 13, 11, and 10 in the three preceding weeks; of these, three resulted from whooping cough, two from "fever," one from measles, and one from scarlet fever, but not any from small pox, diphtheria, or diarrhœa. These seven deaths were equal to an annual rate of 1·0 per 1000, the death-rates from the principal infectious diseases last week being 1·2 in London and 0·6 in Edinburgh. The deaths from whooping cough, which had been five, seven, and four in the three preceding weeks, further declined last week to three. The fatal cases of "fever," which had been four, one, and one in the three preceding weeks, rose last week to two. The 145 deaths in Dublin last week included 26 of children under one year of age and 38 of persons aged 60 years and upwards; the deaths of infants showed a slight decline from the number in the preceding week, while those of elderly persons decreased very considerably. Five inquest cases and two deaths from violence were registered, and 61, or more than 42 per cent., of the deaths occurred in public institutions.

The causes of six, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

Royal Naval Volunteer Reserve.

The undermentioned gentlemen have been appointed surgeons, viz. :—Marcus Sinclair Paterson and Reginald John Edward Hanson (dated Dec. 23rd, 1903).

2nd Life Guards.

Surgeon-Captain J. H. Power, from Royal Horse Guards, to be Surgeon-Major (dated Dec. 21st, 1903).

Royal Army Medical Corps.

Lieutenant-Colonel J. F. Williamson, C.M.G., to be Colonel to complete establishment (dated Dec. 20th, 1903).

Major H. Carr and Lieutenant M. C. Beatty are nominated for service in the Bombay Command, vice Lieutenant-Colonel Birrell and Captain MacDougall, whose tour has expired. Captain J. M. Cuthbert, attached to Agra Station Hospital, is ordered to assume the medical charge of the 17th Infantry (the Loyal Regiment). Lieutenant E. S. Worthington, attached to Agra Station Hospital, is ordered to Jhansi for duty.

Indian Medical Service.

The King has approved of the following promotions made by the Government of India :—Majors to be Lieutenant-Colonels : *Bengal Establishment :* James John Pratt and Robert Shore. *Madras Establishment :* William Burney Bannermann and Henry Thomson. *Bombay Establishment :* Carrapiet John Sarkies.

The King has also approved of the retirement from the service of the undermentioned officers : Lieutenant-Colonel Henry Augustus Fitzroy Nailer (dated Oct. 20th, 1903), Lieutenant-Colonel William Keith Hatch (dated Nov. 15th, 1903), and Lieutenant-Colonel Daniel Francis Barry (dated Dec. 16th, 1903).

Medicine and Sanitation in Morocco.

We learn from recent articles in the *Archives de Médecine Navale* that Dr. Raynaud, the chief sanitary official in Algeria, has embodied the observations that he made during several visits to Morocco in an octavo volume of 205 pages, with plates and a map, which has been published under the auspices of the Governor-General of Algeria. The work is divided into three parts which are devoted respectively to hygiene, medicine, and climatology. The first part comprises four chapters under the following headings : 1. General Hygiene, including ethnology, slavery, marriage, burial, clothing, cosmetics, food, dwellings, physical exercises, and monastic establishments. 2. Public Hygiene, including mosques, baths, markets, conservancy, slaughter houses, sewers, drinking water, cemeteries, prisons, and pilgrimages (Moslem to Mecca and Christian to Jerusalem). 3. Public Assistance, including hospitals and benevolent institutions (in Morocco this branch of civil polity is entirely in the hands of the foreign population). 4. Causes of Depopulation, including famine, epidemics, alcohol, tobacco, *kif* (Indian hemp), opium, and aphrodisiacs. The second part of Dr. Raynaud's book contains seven chapters on the following subjects : 1. Present State of Medicine in Morocco, including medical schools and curricula, text-books, diplomas, *tobibs*, *santons*, talismans and amulets, precious stones and their medicinal properties, and general notions regarding the science of medicine. 2 External Pathology, including surgical instruments, anæsthesia, hypnosis, minor surgery, ophthalmology, and obstetrics. 3 Internal Pathology. 4 Syphilis and Cutaneous Diseases. 5. Therapeutics, including organo-therapy and native drugs. 6. Veterinary Surgery. 7. Arab Medicine.

The Care of Soldiers' Teeth.

Mr. A. F. A. Howe, L.D.S.R.C.S., who read a paper before the October meeting of the Southern Counties Branch of the British Dental Association on the Dental Requirements of the Army, has had his observations reprinted in pamphlet form. It contains, perhaps, nothing that is new, but it is nevertheless a powerful plea for a more adequate recognition of the services of the dentist The old policy of doing nothing for a soldier's they ache and then extracting them is not an procedure. During the late war reserve men jected in consequence of loss of teeth and at the of war many men were temporarily disabled and had to be invalided home in consequence of some the teeth. Then again recruits are rejected who saved to the army if the services of a dentist were In the post office and prison service a candidate otherwise fit is accepted provisionally subject to his or her made serviceable, and the same rule ought to be made regard to recruits, though in this case the expenses would have to be borne by the army. The matter is one of great importance and should receive greater atten has hitherto been given to it.

The Royal Naval Hospital, Plymouth.

The Civil Lord of the Admiralty, who is on a visit tion at Devonport, on Dec. 17th, 1903, paid a visit Royal Naval Hospital where he was received by Inspector-General T. Bolster, Deputy Inspector-General T. D. C. Fleet-Surgeon W. Eames, and Fleet-Surgeon D. J. McNabb. Various departments were inspected, the Trafalgar block, in which temporary arrangements were made a short time ago for the accommodation of tioner sick-berth stewards and where, it is extensive alterations will be carried out to facilitate efficient training of probationers. The lunatic ward general wards were also visited. A scheme for the greater part of the hospital is now being carried

Deaths in the Services.

Surgeon-Colonel Sir George Thomson, K.C.B., Dec. 23rd, in his sixty-first year. He entered the Medical Service in 1865 and was attached to the 4th and 1st Punjab Cavalry. In 1878–79 he served in Afghan war (mentioned in despatches), was medical officer with the Chitral Relief Force on the of communications in 1895 (mentioned in C.B.) and in 1897–98 he acted as principal medical of the Tirah Expeditionary Force (mentioned in and K.C.B.).

"Audi alteram partem."

THE FEES AND EXPENSES OF PUBLIC VACCINATORS IN RURAL DISTRICTS.

To the Editors of The Lancet.

Sirs,—The article by your correspondent on vaccination fees[1] is in no way too strong. I have worked out the figures of payment in my own district for the last four years and they are as follow :—

Year.	Number of vaccinations per year.	Number of visits paid to secure vaccination.	Mileage to secure vaccination.	Average fee per visit.	Average fee per mile.
1900 ...	70	200	800	2s. 0d.	6d.
1901 ...	54	150	600	2s. 4d.	7d.
1902 ...	54	180	720	1s. 9½d.	5½d.
1903 (three quarters)	45	150	600	2s. 2½d.	6½d.

The fees paid to me are the minimum fixed by Local Government Board—viz., 1s. each child who is vaccinated by the end of the fourth month and 5s. f successful vaccination. When we consider that a large proportion of my cases lie many miles from my home, that they must be visited at least twice and many of them more than that, and that the visits must be made by will appear how ridiculously inadequate the fees are. The Local Government Board is, I believe, aware of this hardship but it makes no attempt to protect the interests of public vaccinator unless the public vaccinator appeals it on the establishment of a "contract" with his board of guardians. I am, Sirs, yours faithfully,

---

[1] The Lancet, Dec. 19th, 1903, p. 1759.

Rugby, Dec. 21st, 1903. J. HUTCHINSON.

To the Editors of THE LANCET.

SIRS,—The article on this subject from a correspondent in THE LANCET of Dec. 19th puts the matter very clearly, but there is one point not mentioned by him, or in your annotation in the same issue, which I think in fairness to public vaccinators ought to have received some comment. It is this. Persons (mostly young women) get vaccinated at a surgery and instead of coming for inspection at the appointed time, either do not come at all or else send, generally late in the evening, to say that they are ill and want to be seen at once. Of course, such messages have to be attended to only to find the healthy reaction usual eight to ten days after inoculation and the sole cause of complaint. In the rush of work those who had not returned for inspection could not always be visited and in some instances, owing to wrong addresses having been given, they could not be found. These vaccinations and visits are not paid for.

I once had to attend a patient right through a sharp attack of pneumonia contracted six days after I had vaccinated. When I sent my account it was promptly brought back by the father who told me more plainly than politely that he would not pay; that as I had put the disease in his child it was my duty to get it out; and that if he had thought the illness due to anything else other than the vaccination I should have been the last person he would have had for a medical attendant. As the vaccination had not taken I got nothing except a lot of trouble, expense, and two night calls, to say nothing of the abuse.

I am, Sirs, yours faithfully,

Dec. 21st, 1903. A SEMI-RURAL P. V.

To the Editors of THE LANCET.

SIRS,—Public vaccinators must one and all be grateful to your correspondent who in THE LANCET of Dec. 19th has given such a telling array of facts and figures against the menaced reduction in the present hardly enough earned fees for public vaccination. That the recent "big bills" which guardians have been called upon to pay have been entirely due to revaccinations necessitated by the small-pox scare is strikingly shown by the following figures from a certain union:—

Year.	Primary vaccinations.	Revaccinations.
1900	1018	0
1901	964	1
1902	1028	55
1903	1089	3794

At the present time there are practically no revaccinations and the average of primary vaccinations continues pretty much as it was during the previous four years, so that while the revaccinations have risen from zero to 3794 and have again sunk to zero the primary vaccinations have maintained their average. To base a claim for reduction of the fee for primary vaccination upon the altogether abnormal and temporary increase of the numbers of revaccinations would therefore be most unjust. The two classes of cases are upon an entirely different footing, as the following will show:—

Primary Vaccinations.	*Revaccinations.*
1. The parent must be notified of intention to visit.	1. No notification required
2 The patient must be vaccinated and inspected at home.	2. The patient may be vaccinated at surgery.
3. Patients must be vaccinated upon day of notification and between the hours of 9 A.M. and 4 P.M.	3 May be done any day and at any time.
4. Must be certified.	4. No certificate required
5 Cases occur singly as a rule and often far apart.	5 Often occur in groups and close together.

Comparisons are sometimes made between the fees of the [illegible] public vaccinator, but [illegible] entailed upon each is [illegible] of the differences:—

Private Practitioner.	*Public Vaccinator.*
1. Has no register to keep.	1. Must keep strict record of every case in register of 16 columns for each case.
2. Has no official clerical work	2. Has all sorts of "forms," "notices," "returns," and statistics to make up.
3. Has no unclaimable work. Can charge for every visit, for all medicines, &c.	3. Has a great deal of unremunerative work, such as fruitless visits, unsuccessful cases, postponement certificates, after attendance upon cases, supply of dressings, supply of medicines, &c.
4. Can vaccinate and inspect at surgery at any time.	4. Must vaccinate and inspect all primary vaccinations at their homes between 9 A.M. and 4 P.M.
5. Is not responsible for certification of case.	5 Is responsible for certification.
6 Is under no compulsion *re* asepsis and after treatment, or as regards number of marks.	6. Is under compulsion *re* all of these.
7. Is not under Government inspection.	7. Is under Government inspection.

It is also contended that the vaccination work of the public vaccinator is more efficiently done than that of the private practitioner, and it is a well-known fact that the great majority of "insusceptible" certificates are filled up by the latter.

Another point which ought to be borne in mind is the unpopularity of the work of the public vaccinator and the undoubted loss of practice that is involved in the conscientious performance of his public duty and the vast amount of time that this takes up—time, too, which he can ill spare from his ordinary visiting work. The amount of the latter, in consequence of his inability to attend to it and the unpopularity of his vaccination work, he soon finds diminishing. I therefore hold that any reduction in the present minimum scale of fees would be unjustifiable.

I am, Sirs, yours faithfully,

Dec. 21st, 1903. DELTA.

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—In a former letter (Nov. 7th, p. 1322) I endeavoured to show that pulmonary suction or "tension" (which is much the same thing) depends essentially upon the action of the inspiratory muscles. Dr. Auld in his reply (Nov. 21st, p 1462) adversely criticises my conclusion. While admitting that the muscles of inspiration take part in the initial establishment of pulmonary tension soon after birth, he denies the action of these muscles in maintaining it throughout life; he denies, to use his own words, "that such action is thereafter maintained and perpetuated to a similar purpose" because "the conditions are ...... reversed and the inspiratory muscles instead of endeavouring to establish a pulmonary suction are in reality directed rather against it" I can put no other interpretation upon these words than that Dr. Auld at the time he wrote them meant to imply that the inspiratory muscles, once pulmonary suction is fairly established, do not contribute to the main*tenance* of what we may call the normal average suction and that he had overlooked the fact which I pointed out in my next letter (Nov. 28th, p 1531)—namely, that even in ordinary quiet breathing the effect of the action of the inspiratory muscles is to make the mean size of the chest, and therefore pulmonary suction, greater than they are when breathing ceases in expiration and consequently that these muscles take a life long, *moment by moment*, part in the maintenance of normal average suction. Now how does Dr Auld meet this argument in his last letter (Dec. 5th, p. 1614)? He is surprised that I should "deem it necessary to insist on such an elementary fact as that the inspiratory muscles augment pulmonary suction" The elementary fact I insisted on was the fact, overlooked by Dr. Auld, that so long as breathing lasts the mean of the chest is greater than when the inspiratory muscles cease to *act and that* therefore these muscles constitute a constant factor in the maintenance of normal suction.

Dr. Auld proceeds to repeat his statements to the effect (1) that after the initial establishment of pulmonary suction (or tension) the inspiratory muscles are "directed against this resistance," whereas (2) this is not the case during the initial stretching of the child's lungs. I submit, Sirs, that the first of these propositions is irrelevant and that the second is untrue. 1. Pulmonary tension cannot exist except by the action of forces "directed against" it. It is impossible for the lungs to be stretched by any other means. How, I would ask, can Dr. Auld use this elemental fact to controvert any of my contentions? 2. From the very moment the pulmonary tissue is first put on the stretch *in the smallest conceivable degree* the inspiratory muscles are "directed against" pulmonary tension, which can only come into being as a result of some force or forces thus directed.

I come now to the next point in Dr. Auld's letter. He writes in respect of passive recoil: "If Dr. Campbell *now admits* [my own italics] this factor to be alone competent to produce a certain degree of thoracic expansion," &c., thus suggesting that I have abandoned a position. In point of fact, I was the first to allude to this factor in connexion with the present discussion and have in each of the previous letters in the most precise language of which I am capable maintained its competence to cause thoracic expansion.

In my last letter I argued that Dr. Abrams's contention that the pulmonary margins may by reflex dilatation be made to extend further downwards than by voluntary inspiration must be erroneous, seeing that in the latter way they can be brought to the uttermost confines of the pleuræ, further than which they cannot go—so long, of course, as the pleuræ remain intact. Dr. Auld does not admit the cogency of this argument; he believes it "can be disposed of without much difficulty." He quotes Cunningham to the effect that the pleura does not in ordinary circumstances "dip down to the bottom of the narrow interval between the thoracic wall and the diaphragm," and argues that "after the pleural cavity is fully filled by the lung there remains an interval into which the lung can be stretched." Here Dr. Auld brings out a fact—certainly of great interest—i.e., that the lower confines of the pleuræ are not stationary; but how does this affect the validity of my statement that the lungs cannot pass beyond the confines of the pleura? Whether those confines are fixed or moveable is altogether beside the question. Were my body imprisoned in a vast pleural sac would it be possible, so long as the sac remained intact, for me to pass beyond its uttermost confines, be the sac stretched never so much? But observe into what further impossible position Dr. Auld lands himself. He is all the while implying that while by a deep voluntary inspiration the lungs can only be made to travel as far as (what we may call) the usual confines of the pleuræ, these organs, when relaxed by reflex dilatation, can be made to stretch the pleuræ so that the latter shall extend downwards beyond their wonted limits and, moreover, that all this can be effected by a passive outward recoil of the chest walls! That such can be the case is to me as inconceivable as that the whole is greater than its parts.

Regarding Dr. Albert Abrams's letter (Dec. 19th, p. 1756), I would repeat that I have never denied the existence of a pulmonary reflex of dilatation. I have simply sought to show that much at least of the evidence adduced by Dr. Auld in proof of its existence is open to criticism. Nor do I regard as conclusive the evidence which Dr. Abrams brings forward in favour of the existence of a "counter reflex of lung contraction." He tells us that if the chest be concussed in a certain way there is induced for a few seconds a (local) area of dulness together with a darkening (as shown by the Roentgen rays) in the corresponding region. Dr. Abrams concludes that these phenomena are due to a localised lung contraction. For myself I cannot explain them, but I would raise the question whether they may not be quite as satisfactorily explained on the assumption of a changed condition in the chest wall as on that of changes in the underlying lung. I am not, it is true, able to say how the chest wall can be altered by concussion so as to induce the phenomena in question, but there seem to me to be grave difficulties in the way of referring them to a pulmonary causation. Dr. Abrams postulates a momentary contraction of a limited pulmonary area sufficiently pronounced to cause a local darkening in the fluoroscopic picture and a local area of percussion dulness. Such a contraction could only be induced, so far as I am able to judge, by a primary contraction of the alveoli themselves leading to their complete, or all but complete, obliteration, and the question arises whether such an event is possible. It is true (if I remember aright) that unstriped muscle fibres are found in the alveolar walls, but if the vesicles are susceptible of such extreme contraction it is a fact new to physiology. I need scarcely point out that of the pulmonary tubes the only ones capable of completely shutting off all access of air to the alveoli are the bronchioles. Now even if we suppose that in the area of fluoroscopic darkening the bronchioles are completely obliterated, this does not by any means imply collapse of the air-vesicles belonging to them. Quite the opposite effect, indeed, would be induced, for the contracting bronchioles would drive some of their contained air onwards into the vesicles; moreover, by so much as the tubes diminished in their volume by just so much would the volume of the vesicles tend to increase, so that the related vesicles would actually increase in volume and in the tension of their walls; pointing in the same direction is the further fact that in spasmodic asthma, an affection avowedly due to narrowing of the tubes, the lungs expand, while the chest becomes *hyper-* rather than *hypo* resonant.

May I, in conclusion, Sirs, introduce an entirely new consideration regarding the question of a lung reflex? One of the contentions of Dr. Abrams and his disciples is that by stimulating a limited part of the chest wall the subjacent lung can reflexly be made to expand, so that when, e g., the præcordium is stimulated the pulmonary margins near the heart will move more extensively than those more distantly situated. Now I would point out in this connexion that inasmuch as pulmonary tension tends to be equal in all parts of the lung, when a limited area of pulmonary tissue is relaxed the remaining more tightly stretched portions will drag upon the relaxed portion until it is stretched in an equal degree with them, a circumstance which must tend to prevent the pulmonary margins moving more in the region of the area reflexly affected than in other parts.

I am, Sirs, yours faithfully,

Wimpole-street, Dec. 27th, 1903. HARRY CAMPBELL.

THE BORDERLANDS OF INFECTIOUS DISEASES AND THEIR MANAGEMENT.

To the Editors of THE LANCET.

SIRS,—I certainly resented, and do still resent, the language used by Dr. C. Dukes in his letter dated Nov. 14th. His words imputed apathy and callousness to all those who like myself have to do with the management of fever hospitals and implied that little, if any, attention had been paid to what I have elsewhere termed "isolation within isolation"—the provision in fever hospitals of quarantine and observation rooms. Dr. Dukes in that letter made no distinction between one fever hospital and another; the responsible managers of all were included in one sweeping condemnation. Therefore I resented, and I think I may say justly resented, the attack he made; nor, in my opinion, has he in his last letter added anything to justify his action.

With respect to the hypothetical instance put to me by Dr. Dukes, curiously enough he has succeeded in imagining a very out-of-the-way case. In the first place, it is very unusual for equivocal cases of scarlet fever resembling diphtheria to be sent to hospital as scarlet fever, so that such cases do not get sent to the diphtheria wards. Secondly, supposing that such a case did resemble diphtheria and was sent to the diphtheria wards, strange as it may seem, the chances of the patient getting diphtheria are very remote. The most likely occurrence would be, not that the particular equivocal case would contract any second infection, but that some of the other patients in the ward would catch scarlet fever. I have no desire, however, to shirk the question and I will take the case of a child who, admitted to hospital with one disease, contracts another, from which he dies, and I suppose that this is the sort of case that Dr. Dukes really means. As to whether the use of strong language is necessitated or justified depends entirely upon the circumstances. The occurrence may or may not be the fault of the hospital authorities. What I resent is that Dr. Dukes assumes that it is always and everywhere their fault, whereas I assert that the reverse is the case.

I must thank Dr. Dukes for the candour with which he has admitted that his experience of infectious diseases is limited, for he has informed us that it has been confined principally to observations on cases that have occurred during a period of several years in a school of 700 males between the ages of nine and 19 years, these males, moreover, being members of the well-to-do classes of society. I need hardly point out that the bulk of cases of infectious disease (except typhoid fever and nowadays small-pox) occur in children under ten years of age and of the poorer classes, and that it is in young children rather than adolescents that they appear in their protean and severe forms. So I can quite understand how it is that Dr. Dukes has never come across any of the ases described by Dr. H. E. J. Biss under the term "border-and." The description given by Dr. Biss of these cases is ccurate enough; they are quite familiar to those of us who ave had the opportunity of studying infectious diseases in arge cities. I am, Sirs, yours faithfully,

Homerton, Dec. 27th, 1903. E. W. GOODALL.

To the Editors of THE LANCET.

SIRS,—Dr. Clement Dukes, in his letter dated Dec. 18th, writes: "I regret that I am not prepared to follow the lead of Dr Biss and support Dr. C. K. Millard in his proposal for an inquiry into fever hospitals, inasmuch as his aim is to end hese valuable institutions, whereas mine is to mend them."

Allow me to say that Dr. Dukes scarcely represents my attitude correctly. It may be true that some have condemned solation hospitals as being radically wrong in principle and have advocated their entire abolition, but I have never gone so far as this. I have carefully avoided condemning isolation hospitals *in toto* and have purposely restricted myself to asking for an inquiry. Moreover, I have confined myself to the case of a single disease—viz, scarlet fever.

Of course, in order to make out a case for an inquiry I have had to call attention to certain facts which undoubtedly appear to tell strongly against hospital isolation. Thus I have pointed out that it is very difficult, if not impossible, to find any satisfactory evidence that fever hospitals, as worked in the past, have done any real good. On the other hand, I have adduced some evidence which suggests that they may to some extent have actually done harm. I have called attention to the baneful influence of "return cases" and to the dangers of cross infection, &c. I have also tried to show that it is much more practicable to treat scarlet fever at home than is usually supposed. But all this has been urged avowedly as ground for an inquiry. If the indictment makes the case for hospital isolation look rather bad that is scarcely my fault. It only shows how desirable it is that an inquiry should be held. It is surely as unjust to accuse those who ask for an inquiry into the working of isolation hospitals of wishing to put an end to them as it would be to accuse a bench of magistrates of wishing to get a man hung whom they had committed on a capital charge. As Dr. Biss has well said, if isolation hospitals will bear investigation they have nothing to fear from an inquiry and they will emerge from the ordeal more firmly established than ever. If, on the other hand, they will not bear investigation, then the sooner a full and searching inquiry is held by some competent body the better it will be. This is so obvious that it is really extraordinary that such an inquiry was not held at once when the utility of isolation hospitals was first challenged some years ago.

As a matter of fact, Dr. Dukes, although he says he is unable to support the proposal for an inquiry, is almost as sweeping in his condemnation of isolation hospitals as anyone I know. In his first letter[1] he wrote: "The sooner, then, isolation hospitals, which apparently are not isolation hospitals but disease-developers, are mended or ended, the more creditable will it be for us as a profession and the safer will they be for the public."

It is true that he proceeds to give what he believes to be the remedy, but, even though he may be right in this, it is scarcely likely that the mere opinion of one man will carry very much weight in a great question such as this is, and the evils of which he complains will almost certainly continue. Dr. Dukes rightly says that "the question of the influence of fever hospitals is a burning one at the present time." In other words, very great difference of opinion exists amongst experts as to what the influence of fever hospitals really is. Certainly a very great change in opinion has taken place within the past few years. When the movement against isolation hospitals was first started by Mr. E. D Marriott of Nottingham some five years ago it was treated with indifference and contempt, if not with ridicule The value of isolation hospitals had been so completely taken for granted that few had taken the trouble to inquire into it. Now, however, it is very different. Several medical officers of health of high standing and others well qualified to form an opinion on the subject have expressed themselves as being very doubtful as to the wisdom of the policy which has hitherto been pursued as regards hospital isolation. Others are looking into the subject *de novo*, whilst very few, I think, would now be prepared to speak dogmatically about the "enormous and undoubted value" of fever hospitals as was formerly the case.

But, unfortunately, whilst all this uncertainty and doubt is steadily increasing, fresh hospitals continue to be built on the old lines, at great expense, out of loans which will have [illegible] of the future. Whether they [illegible] y of debt is another matter. It is for this reason that some of us regard this question as one of urgency and think it desirable that the whole subject of hospital isolation should be fully and thoroughly investigated, by special commission or otherwise, with as little delay as possible.

I am, Sirs, yours faithfully,

Town-hall, Leicester, Dec. 28th, 1903. C. KILLICK MILLARD.

To the Editors of THE LANCET.

SIRS,—The article by Dr. H. E. J Biss on the Borderlands of Diphtheria and Scarlet Fever, together with the subsequent correspondence aroused by it in your columns, illustrate one of the difficulties constantly experienced in the administration of isolation hospitals I have for years, doubtless in company with other medical officers of health, pinned my faith on the isolation hospital as one of the chief factors for the prevention of scarlet fever. I accepted the dicta of the leading public health authorities, backed as they were by the Local Government Board, on the value of the isolation hospital without hesitation and without criticism; the theory seemed to me sound and if I did not get the results hoped for I concluded the fault must lie in some unrecognised conditions which would in due course be explained and remedied.

In recent years, however, articles by Mr. E Dean Marriott and Dr. C. Killick Millard have caused me to investigate the subject more carefully for myself. Mr. Marriott has expressed the opinion that isolation hospitals, so far from limiting the disease, actually tend to increase its prevalence Dr Millard, basing his opinions on statistics collected from all the large towns of the kingdom, showed that towns isolating only a few of their scarlet fever cases in hospital suffered no more, and often not so much, from that disease than those towns which went to the expense of isolating 70, 80, or 90 per cent of the cases. Now, neither Mr. Marriott's nor Dr Millard's arguments have been refuted. Dr. Millard's paper was read before the Incorporated Society of Medical Officers of Health, a body of men who were above all others qualified by their experience to correct and detect any fallacies in his arguments. The only serious attempt to controvert his facts was made by Dr. J. R Kaye who produced a laboriously constructed paper in which, however, he was only able to detect a trifling error in one set of Dr. Millard's figures

As medical officer of health of one of the large towns I have had the opportunity for some years of studying the effect of isolation hospitals in controlling scarlet fever, and I confess that the result of my observation has been such that I have felt compelled to advise my authority against further expenditure in this direction. Further, while there may not at present be other medical officers of health who have gone so far as this, yet I feel convinced that there are numbers who are much exercised in their own minds on this question. The fact that isolation hospitals have failed to accomplish what was sanguinely anticipated at their inception will not, I think, be denied even by their most enthusiastic supporters. What, then, is the reason for this failure? Is it, as maintained by some, due to the faults of administration, or are the theories, upon which the success of the system depends, at variance with the actual facts as they occur in practice? For in connexion with this latter alternative it must not be lost sight of that although the isolation hospital for the control of scarlet fever has been in vogue for 20 years or more its general employment throughout the country was not based on the result of experience but upon theory. In support of this theory millions of money have been expended—in fact, neither money, time, nor trouble has been spared to render the isolation hospital a success.

Now, Sirs, it seems to me very desirable, in the interest not only of the medical profession but also of the public, that an inquiry into the subject should be instituted, and I believe you would be rendering a marked service if you would open the columns of THE LANCET with a view to ascertaining the opinions of medical men on this matter.

---

[1] THE LANCET, Nov. 28th, 1903, p. 1529.

After all these years there must be a mass of evidence obtainable, the careful consideration of which by an authoritative body of men should result in a report which could not fail to be of immense value. Possibly such a report would find that the isolation hospital was not so beneficial as is generally conceded; on the other hand, it might indicate improved methods of administration whereby the usefulness of such institutions could be greatly enhanced. In any case such an inquiry can do no harm and, in view of the diversity of opinion on the effect of the isolation hospital in controlling scarlet fever, appears to me eminently desirable.

I am, Sirs, yours faithfully,
A. MEARNS FRASER, M D.,
Medical Officer of Health, Portsmouth.

Portsmouth, Dec. 22nd, 1903.

WATER-CRESS AND TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—I have read with interest the admirable report of Dr. J. King Warry on an outbreak of typhoid fever in Hackney in June last and also your editorial comment in THE LANCET of Dec. 12th, p 1671, and lastly the criticism of Dr William Bruce in THE LANCET of Dec. 26th, p. 1834. May I say at once that in my opinion Dr. Warry's conclusions appear to be amply justified by the facts he has collated and that Dr. Bruce's criticism appears to me to be an apt illustration of a logical fallacy.

Dr. Bruce says: "If eating water-cress was the real reason of the outbreak surely the first evidence would require to be that *everyone* attacked partook of the article in question." (The italics are mine.) How can Dr. Bruce advance this argument when he believes (as, indeed, all persons with any considerable experience of typhoid fever *know*) that the disease is frequently "spread by infection from person to person." Surely the earlier cases in Hackney may have been infected by the polluted water-cress while some of the later cases may have been cases of personal infection and yet some of them indirectly attributable to the infected water-cress. Considering the various channels by which the typhoid bacillus may reach the alimentary canal it is preposterous to advance the view that everyone attacked should have partaken of the suspected article. Some of the cases were probably quite independent of the water-cress. I do not suppose for a moment that Dr. Warry suggests that the whole of the cases were traceable to the polluted water-cress but merely that that infected article was the origin of the excess of typhoid fever in June, 1903, as compared with the average June incidence in previous years.

Dr. Bruce does not seem able to grasp how one sample of water-cress may be infected and another innocuous, even though both may be obtained from the same polluted source In the first place, typhoid bacilli are particulate matter in suspension (and *not in solution*) in the contaminated water; they are not, therefore, present in every drop or cubic centimetre, or even litre, of the contaminated water; hence *only portions* of the water-cress growing in the sewage-polluted stream become contaminated with typhoid bacilli. In the second place, even an infected portion of water cress may be rendered innocuous by being very thoroughly washed under a running tap. Some persons are more careful and cleanly than others and wash their water-cress more thoroughly. Such persons may thus get rid of the particulate pathogenic bacteria by the mechanical force of a stream of water. Dr. Bruce again says: "The specific bacillus has never once been demonstrated as present in any single sample of suspected water." Though I would be extremely cautious as to the use of the word "never" it may be granted that it would be quite exceptional to find the typhoid bacillus in a suspected water. Has Dr. Bruce never reasoned as to why this is so?

I have already shown above that not every litre of a contaminated water would necessarily contain a few particulate bacilli, while most bacterioscopical examinations of water are carried out with only fractions of a cubic centimetre. Apart from this consideration it is a question to be decided whether the specific pollution of the water is a continuous pollution or was of a past and temporary nature. More often it is the latter and by the time that cases of typhoid fever have arisen in sufficient numbers to cause suspicion to be attached to a particular water-supply several weeks have probably elapsed since the date of specific pollution. It is therefore not a matter for surprise if the specific bacillus is not to be found, but if the bacterial examinations afford ground for suspecting the presence of sewage pollution (even if the specific bacillus is not isolated from the small quantities which only can be plated out) the likelihood of the suspected water being the probable vehicle of the poison is greatly strengthened.

Again, as regards shell-fi [illegible] no means every shell-fish [illegible] particulate specific bacter [illegible] imbibe a particular porti [illegible] The typhoid bacillus *has* [illegible] shell-fish but the majorit [illegible] the same layings reveal [illegible] sewage bacteria All, [illegible] Just so with water-cres [illegible] actually infected with t [illegible] sidered as potentially [illegible] from previous cases is under-estimat [illegible] assert and on this point I am in agreement with D[illegible]

In my annual report on the health of the borough of Southend-on Sea and again in a paper which I read before the Royal Institute of Public Health at Liverpool in July 1903, I have reiterated the following precautions which I think if followed would very greatly reduce what I term the "residual" typhoid fever in this country: 1. By avoiding *the touching* as well as the *eating of all forms of* shell-fish except such as are beyond any suspicion of pollution. 2. By avoiding the eating of any uncooked vegetables (such as water-cress) which have been subjected to manurial or sewage pollution. 3 By the early removal to hospital of any case of typhoid fever which may occur (a large proportion of cases are secondary consequent upon the nursing of patients by untrained relatives). 4. By careful and constant attention to effective sewage schemes and to frequent and effective disposal of trade and house refuse, &c. 5 By all forms of cleanliness, which must apply particularly to our water-, milk, and other food-supplies and more particularly to shell-fish and water-cress than hitherto. To these I may add another which I mentioned in my annual report for 1901. 6. The routine administration to typhoid fever patients of urotropin before they pass from professional observation. Yet a seventh preventive measure is—Warning convalescent patients of the possibility of their excreta being infective for a considerable time after recovery and instructing them in simple methods of disinfection and other precautions to be observed.

I am, Sirs, yours faithfully,
J. T. C. NASH, M.D. Edin., D.P.H. Camb.,
Medical Officer of Health, Borough of Southend-on-Sea.

Wimpole street, W., Dec. 24th, 1903. [illegible]

THE SIMULTANEOUS OCCURRENCE OF TWO ACUTELY DEVELOPED CUTANEOUS LESIONS.

To the Editors of THE LANCET.

SIRS,—The interesting case of concurrent psoriasis [illegible] erythema nodosum described by Dr. H. W. Syers in THE LANCET of Dec. 19th, p. 1718, furnishes yet another illustration of the principle of co-existence in diseases of the skin. The possibility of the development of two, or even more, acute cutaneous disorders side by side is one which is very apt to be *overlooked* clinically, but it is a fact that this association occurs more frequently than is generally believed. I have been accustomed to divide the cases into those of: (1) natural—i.e., causally related; and (2) accidental association. As an instance of the former may be mentioned the acute development of alopecia with a seborrhœic dermatitis upon the trunk, while as an illustration of the latter I may refer to a case which I have described in detail elsewhere[1] of a man, aged 40 years, who came to the skin department of the Tottenham Hospital suffering from an acute attack of psoriasis. Within a short time he developed an eruption of secondary syphilis which was perfectly distinct and separate from his psoriasis, his skin presenting a most unusual spectacle. Curiously enough, it is psoriasis, the "disease of the healthy," which most often co-exists with other independent cutaneous affections and it is generally the one first in the field, the second disease appearing shortly after its efflorescence. Syphilis, purpura, and leprosy have all been observed to co-exist with psoriasis, but, with the exception of the first, they are rare. In Dr. Syers's case the erythema nodosum appears to have developed quite simultaneously with the psoriasis. Although there was no history of rheumatism in the case, yet it will be admitted that the concurrence of two such cutaneous disorders, both of which are so frequently associated, directly or indirectly, with that disease would form a strong reason for treating such a case with salicin or the salicylates. As was originally pointed out by Dr. Radcliffe Crocker, these remedies often exert a favourable influence upon the course of psoriasis alone. Regarded from the diathetic standpoint Dr. Syers's case would fall into the category of my first group—namely, those concurrently developed acute cutaneous disorders which are "naturally" associated through a more or less causal relationship.

I am, Sirs, yours faithfully,
G. NORMAN MEACHEN, M.D., M.R.C.P. Lond.

MALIGNANT GROWTHS AND NORMAL REPRODUCTIVE TISSUES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 26th, p. 1830, you give a very full account of the interesting paper recently communicated to the Royal Society by Professor J. B. Farmer, Mr. J. E. S. Moore, and Mr. C. E. Walker in which they dwell on the resemblances between certain of the cells of malignant growths in man and those of normal reproductive tissues, and from which resemblances *they draw the conclusion* that the malignancy of these tumours is intimately connected with the reduction of the normal somatic cells into reproductive or germinal tissue. To me this communication is of special interest as I have already put forward a similar view in my paper on Inoperable Mammary Carcinoma read before the Edinburgh Medico-Chirurgical Society in May, 1896, and published *in extenso* in THE LANCET of July 11th and 18th of that year. I there say, when dealing with the etiology of cancer, that "in whatever way brought about there seems to me a reasonable ground for thinking that the active processes seen in a cancerous tumour are best explained by regarding the epithelium of the part as having taken on the properties and powers of the germinal epithelium." I further expressed the belief that the special cells seen in sections or scrapings of cancer and known as "cancer bodies" may eventually be shown to be special germinal cells corresponding to the ovum cells elaborated by the ovary in the female and by the testis in the male

While Professor Farmer and his coadjutors seem to have come to the same conclusion as the result of their microscopical inquiry I did so clinically and chiefly in consequence of the results obtained by oöphorectomy in inoperable mammary cancer. Under that procedure cancerous activity has been arrested and proved cancerous tissue has disappeared with, in addition, diminution of pain and improvement in the general health, a state of matters that has never before been observed in this disease under any other medication and that, too, in advanced cases of the malady. In writing thus I am not giving only my own individual experience. Other surgeons have observed the same results. Unfortunately, I think, the *profession has regarded* this method of treatment from a therapeutic aspect only and judged it solely by the standard of its value as a *curative* agent. This is, of course, quite right, but whatever be the final decision on this point *I would fain hope that the effects following oöphorectomy* will not be lost sight of, especially as we are dealing with a disease the true nature of which has, so far, baffled inquiry. To cause cancerous tissue and cancerous glands to disappear is a very remarkable fact and one that should have more importance attached to it than it has yet had, for I look upon it as furnishing a clue to the real nature of cancer and as strongly confirmatory of the opinion I expressed in May, 1896, "that the disease consists in the epithelium of the part affected taking on the active proliferation which is the marked characteristic of the germinal epithelium." The observations of Professor Farmer and his coadjutors seem to support this view of mine, which, however, was arrived at by a different line of inquiry.

I am not sure that Professor Farmer and Mr. Moore and Mr Walker are altogether correct in the statement they make as to the exact mode of development of the special cells to which they give the term "gametogenic," but a letter such as this is not the place to go into such a question. The mere establishment of the presence of such cells in malignant tissue is a point of the greatest importance and strongly corroborative of what I may call the *germinal-cell theory* of cancer.

I am, Sirs, yours faithfully,
Glasgow, Dec. 27th, 1903. GEORGE THOS. BEATSON.

THE LATE FLEET-SURGEON KIRKER, R.N.

To the Editors of THE LANCET.

SIRS,—In the sympathetic notices of the late Fleet-Surgeon Gilbert Kirker no mention seems to have been made of that officer's work on the effects of the modern rifle bullet of small bore. Dr Kirker's observations were communicated by the late Professor T. Longmore to the Section of Military Medicine and Surgery of the International Medical Congress of 1881 and have since lain buried in the ponderous volumes of the Transactions of that meeting[1] A careful study of his paper, entitled "A Comparison of the Cylindro conoidal and Round Bullet Wounds," would have rendered many of us less free in the expression of surprise at the results of the modern bullet wound as observed in the late war. The late Dr. Kirker, I know, felt that his work had scarcely obtained the recognition it deserved and it seems only right that, although late, attention should be drawn to his pioneer work in this direction

I am, Sirs, yours faithfully,
G. H. MAKINS.

THE FUNCTIONS OF THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—In reference to your frequent allusions to rampant quackery, is it not possible for the General Medical Council to take some practical steps for the protection of the medical profession and the public? No doubt the Council's work is good as far as it goes but I express the feeling of many other medical men when I say that we think the professional needs of our class do not receive adequate attention. You say in your section of the Annus Medicus dealing with the Council that the preliminary education of the student and the consideration of penal cases have absorbed all the time that the Council can afford to give to its deliberations. In that case Parliament should grant a subsidy to the Council, for it is clear that other subjects remain for discussion and no less clear that there are abuses to be reformed.

I am, Sirs, yours faithfully,
M D CANTAB.
Dec. 28th, 1903.

*** Our correspondent will find his question dealt with in a leading article on p. 37.—ED. L.

THE UNIVERSITY OF LONDON AND MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—Your leading article, which appeared under this title on Dec. 19th, 1903, sufficiently indicates the great educational work which lies before the reconstituted University of London as well as the extreme importance of that work to the medical profession.

While congratulating the University of London upon the substantial progress it is making towards improving the conditions under which its undergraduates will in the future study for degrees in medicine, medical men, whether members of the corporations or not, must all regret that there are no indications that the Royal College of Physicians of London and the Royal College of Surgeons of England are sufficiently alive to the necessity of keeping pace with educational progress. The attempt now about to be made to improve the courses of study and examinations in preliminary science for their conjoint diploma has been so long delayed that the Colleges will not get due credit for it. The antipathy of the Colleges to accede to any outside influence or to modify any of their existing regulations causes almost despair as to any ultimate agreement between these bodies and the University with the object of lessening the number of examinations to which the unfortunate London student of medicine has now to submit. It is much to be hoped, however, that a further attempt in this direction may still be made. It is true that the Colleges have reported adversely to the proposal to endeavour to secure concerted action with the University in the conduct of examinations. This decision was arrived at, however, before the Faculty of Medicine had resolved to advise the Senate to endeavour to enter into negotiations with the Colleges for this specific purpose. The Colleges I should hope may be relied on to consider favourably a definite proposal emanating from the Senate. Every forward step taken by the University makes it more evident that if the Colleges hold aloof from the University they must surely and steadily lose ground as a controlling influence upon medical education in London. The Colleges have in the past done their best to compensate the London student of medicine for the absence of a teaching university in this city. It should not be beyond the power of senators and councillors to arrange for these ancient corporations and the modern university to work shoulder to shoulder to their mutual honour and to the advancement of London as a centre of medical education and research.

[1] Medical Press and Circular, vol. i., 1902, p. 773.

[1] Transactions of the International Medical Congress, 1881, vol. ii., p. 578.

The removal to a central institution of facilities for instruction in preliminary or ancillary sciences will not deprive our hospital schools of their prestige. It will rather give them opportunities for using to the advantage of their students the unrivalled clinical material provided by their crowded wards. The medical schools proper of the metropolis will be the gainers if the scheme of concentration advanced by Lord Rosebery and his colleagues receives support. The fact that King's College Hospital proposes to move to a site a long way distant from the College where its prospective students will study anatomy and physiology, is an object lesson which should prove to the governors of other hospitals that dissecting rooms and physiological laboratories are not necessary adjuncts to the wards of a hospital in which medical education is conducted.

I am, Sirs, yours faithfully,
Dec. 30th, 1903. PHYSICIAN AND TEACHER.

THE ASSURANCE OF UNDER-AVERAGE LIVES.

To the Editors of THE LANCET.

SIRS,—I will try to meet Dr. R. L. Guthrie's suggestion in his letter in THE LANCET of Dec. 19th, 1903, p. 1758, and throw some little light on the question of extra premiums as affected by the different scales on which the normal whole life assurance premiums may be paid. Extra risks have already been roughly classified under three types: (1) those of a *decreasing* or *immediate* nature, such as, e.g., arise from a consumptive family history or a past illness the complete recovery from which may be doubtful; (2) those which operate more or less *uniformly* throughout life, e g., the risk of death by accident in the course of a hazardous occupation; and (3) the category of *increasing* or *deferred* risks, under which I suppose would be classed those of a gouty or cancerous nature mentioned by Dr Guthrie.

In the absence of statistics showing the actual incidence and distribution of the several types of extra risk one has to fall back on hypotheses more or less arbitrary. I have taken the Institute of Actuaries (Hm) Table and increased the annual death rates as follows: firstly, by an addition of 1 per cent. per annum for the first ten years of assurance with normal rates thereafter to correspond roughly with type (1); secondly, by a uniform addition of ½ per cent. throughout life, giving a whole-of-life extra practically equa in amount to that in the first case; and thirdly, by an addition of 1 per cent. at the ages between 40 and 50 years with normal rates between 30 and 40 and after 50 years, by way of a rough approximation to type (3). The resulting extras for three different scales of premiums are as follows:—

AGE AT DATE OF ASSURANCE 30 YEARS.

	Whole life. £ s d	20 payments. £ s. d.	10 payments. £ s. d.
Type (1), Decreasing Extra Risk.			
Sub normal	2 5 2	3 5 9	5 7 6
Normal	1 17 8	2 15 3	4 12 6
Extra	0 7 6	0 10 6	0 15 0
Type (2), Uniform Extra Risk.			
Sub-normal	2 5 2	3 4 3	5 5 0
Normal	1 17 8	2 15 3	4 12 6
Extra	0 7 6	0 9 0	0 12 6
Type (3), Increasing Extra Risk.			
Sub-normal	2 1 8	3 0 0	4 18 6
Normal	1 17 8	2 15 3	4 12 6
Extra	0 4 0	0 4 9	0 6 0

These results bear out my remarks that in general th whole of life extra requires to be increased for a limite payment scale—that is if my arbitrary modifications from which the results are derived are admitted to correspon roughly with the recognised types of extra risk. Type (3 requires the smallest surcharge for an extra risk of simila aggregate amount to the others, and the deferment of th risk has a decided tendency to reduce the 20 payments extra to the level of the whole life extra. This does not hol good, however, in the case of a less number of payments in other words, such a rule as "the higher the rate o premium the lower the extra" would not seem to be theoretically sound. The principle is rather the reverse unde each type.

I must point out, however, that these results are not new They were brought out in a valuable paper read in 1884 b Mr. F. W. White, F I.A., and Mr. J. H. Whittall, F.I.A. before the Institute of Actuaries.[1] My own hypothetica tables are constructed on the same lines as those followed much more elaborately, by those actuaries. They dra attention, I think for the first time, to the increased extra required on the higher scales and add: "We attach considerable importance to this fact, as the enhanced amoun of the premium payable for a limited number of years no infrequently has the effect we believe of rendering the tru bearing of the extra risk very obscure and, in some minds of even hiding it altogether."

Of course, such discussions must be more or less academi until authoritative statistics of extra risk are compiled Surely the time is not far distant when, as suggested by Mr N. B. Gunn, the president of the Faculty of Actuaries, in hi recent inaugural address, the life offices might extract the results of their experience of under-average lives, with a view to their being classified according to some well-considered system devised by actuarial in conjunction with medical skill. The difficulties in the way are undoubtedly great, but I hardly think they would prove insuperable And any attempt to lighten the dark in which we stand at present in this matter of extra risks is to be desiderated.

I am, Sirs, yours faithfully,
Dec. 22nd, 1903. ACTUARY.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The System of Rapid Filtration of Water.—The Plague Mortality.—Original Research on the Origin of Plague. —The New Plague Policy in the Punjab.—The Insanitary Condition of Madras.

THE American method for the rapid filtration of water known as the Jewell system has been recently installed at the Kolar goldfields. It requires a subsidence basin, filter, mechanical washer, coagulant feed pump, and clear water basin. The water-supply for these fields is from the surface and the water is collected in a tank. Where there is available room it is difficult to see what advantage this system possesses over the slower ordinary process of sand filtration. It has not, I believe, been previously tried on any scale in

---

[1] Journal of the Institute of Actuaries, vol. xxiv.

India. The preliminary addition of alum to the water in the subsidence basin to the extent of at least two grains per gallon is generally considered a disadvantage. In Calcutta or Bombay, for example, something like two and a half tons of alum would have to be used daily.

The plague mortality for the week ending Nov. 28th amounted to 17,617—a slight decrease as compared with the previous seven days. For the corresponding week last year there were only 8915 deaths. The details are: Bombay city, 47[illegible]; Bombay Presidency, 9791; Karachi, 8; Madras Presidency, 264; Calcutta, 22; Bengal, 685; United Provinces, 1819; Punjab, 1154; Central Provinces, 2051; Mysore, 673; Hyderabad, 792; and Central India, 975. The disease is rapidly developing again in Bengal, more particularly in the Patna district, but there are at present no signs of a recrudescence either in Calcutta or Bombay city.

After the existence of plague in the Bombay Presidency for seven years the Government has deputed two officers to devote themselves to the discovery of the relation of plague outside the body to the organism associated with the disease in its clinical aspect. Dr. J. A. Turner of Bombay has joined the ranks of those few who have recognised the inefficacy of the disinfecting measures hitherto adopted but he has also clearly pointed out that neither all the commissions nor other investigators have thrown light on the origin of the disease or on its control. The Government still keep silent [illegible] unjab also recognises the [illegible] It is for the future to be but sparingly employed and then only when the people ask for it. The people are to use it themselves in their own [illegible] ves are to be made available. [illegible] the movements of the people [illegible] e no road or rail inspections and as it is thought that the religious feelings of the people are opposed to the destruction of rats no expense will be incurred on this head. We may safely say that for this large province plague measures are to be abandoned and the disease will be permitted to follow its course absolutely unchecked.

The insanitary condition of Madras is again attracting the attention of Government. The conservancy of the city is put out to contract instead of being directly managed by the corporation. The Tinnevelly settlement of the city is particularly bad. It is here that paddy boiling is largely carried on, the liquid of which is no better than sewage Government also calls attention to the water and the need for a pure and adequate supply. The drainage scheme is not yet completed.

Dec. 10th, 1903.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Musical Festival.

THE results of this triennial affair can now be estimated, as the final meeting of the general committee has recently been held, Earl Howe, the President of the festival, occupying the chair. From the musical point of view the critics seem to be agreed that it was a more successful performance than that of 1900, Elgar's *Apostles* having proved a very attractive piece of work. On the other hand, from the pecuniary point of view, the General Hospital comes off worse than usual and the sum handed over to it compares especially unfavourably with that of the last festival, when there was a larger surplus than at any other festival held under modern conditions. The falling off in revenue on this occasion is due to the smaller number of serial tickets subscribed for. The donations, on the other hand, have considerably increased; indeed, as will be seen from the statement, had it not been for this source of income there would have been but a very trivial sum to be handed over to the hospital. The total sum derived from the sale of tickets was £9786 5*s.* The donations and collections during and after the festival realised £3851 19*s.* 4*d.* and some minor items brought the entire receipts up to £14,007 11*s.* 1*d.* This amount is £1275 5*s.* less than the amount received in 1900. On the other hand, the expenses, which amounted to £9486 7*s.* 6*d.*, were £212 17*s.* in excess of those of the previous occasion. The amount of the cheque handed over to the treasurer of the General Hospital was £4521 3*s.* 7*d.*, from which it will be seen that the net profit to the hospital, apart from the donations and subscriptions, was under £1000.

Hospital Sunday.

The proceeds of this collection have recently been handed over to the representatives of the different hospitals benefiting by it. The General Hospital, the Queen's Hospital, and the amalgamated charities each have a year in turn and this year the last-named group has been the recipient of the sums subscribed. The total amount of the church subscription was £4493 1*s.* 11*d.*, which is a record for the amalgamated charities; in fact, since 1859 this sum has only four times been exceeded, twice on the occasion of collections for the General Hospital and twice for the Queen's Hospital. The largest sum allotted to any single institution was £557 5*s.* 9*d.* which went to the Eye Hospital, and the smallest was £61 13*s.* 4*d.* which was the contribution to the Lying-in Charity.

Mentally Defective Children.

Mrs. Pinsent, chairman of the special schools subcommittee of the Birmingham education committee, has recently read a paper on the above subject before the Birmingham Branch of the British Child Study Association. Mrs Pinsent called attention to the alarming amount of mental deficiency which existed and to the fact that it was increasing. This increase not merely affected the easily recognised cases of lunacy and imbecility but also a class of persons who could not be described as lunatics but who were yet mentally, and very frequently also morally, deficient. These persons were allowed to live in complete freedom, and so far as the law was concerned were supposed to be responsible for their own actions. Many of them were to be found in prisons and many of them in the wards of workhouse infirmaries. At present there were 335 persons described as feeble-minded and epileptic in the Winston Green Workhouse Infirmary. The problem that the lecturer wished the meeting to consider was that of the most humane and economical method of dealing with this class of persons. The first school for children of this class was opened in Germany in 1863. The results attained there were good, for a large percentage of the children turned out were capable of subsequently supporting themselves. In 1893 a class of a similar character was formed in Leicester, that being the first in the United Kingdom. Shortly afterwards work of the same kind was taken up in London and now a number of towns were provided with classes for mentally deficient children. One of the first difficulties met with in the organisation of such classes was the accurate definition of the kind of child who might reasonably be considered to be admissible to them. This question as to the standard of admission must always remain one of considerable difficulty, but the Act under which these classes were constituted was one which permitted of a fairly wide interpretation. According to the lecturer, all children for whom there was any hope at all were given a fair trial in these classes, while some who after admission to them had proved themselves to be very nearly normal children were drafted back again to ordinary schools. The work in the special classes was carefully planned to draw out and to develop any little intelligence which the children might possess. Very few accurate statistics had yet been recorded, but, so far as could at present be judged, the work of the special classes, though excellent as a beginning, did not go far enough It failed in two important particulars. In the first place, when they left school the vast majority of the pupils were quite unable to support themselves, and in the next at the age of 16 years such children were allowed complete liberty of action and freedom from school or other constraint, although mentally they were not above, if equal to, the level of most children six or seven years of age. In Birmingham an "after-care" committee had been formed to, keep a record of every case that left the special classes, with a view of ascertaining (1) how many became wholly or partially self-supporting; (2) how many became morally responsible; and (3) how many had children. The analysis of the cases showed results which were not very encouraging and seemed to point to the conclusion that further and permanent provision was necessary for this class of persons. Out of 46 on the committee's books 18 were at work and earning an average weekly wage of 7*s.* 1*d.* and only eight were thought to have any chance of becoming self supporting. This amounted to 17 per cent. and showed that so far as the remaining 83 per cent. were concerned the work done in the special classes was not sufficient, in fact, did not go far enough. Those who were concerned with the after-care of these children had come to the conclusion (1) that boarding schools should be provided for certain mentally deficient children; (2) that the city councils and boards of guardians should be asked to establish colonies to which these children could be drafted at the age of 16 years; and (3) that as in Birmingham there was no proper accommodation for idiot and imbecile children, it was necessary for the question of providing such accommodation to be placed before the proper authorities.

Staffordshire Consumptive Sanatorium.

This scheme, which has already been mentioned by me in a former letter, seems to be meeting with a good deal of opposition throughout the county. Lord Lichfield, who is chairman of the sanatorium subcommittee of the Staffordshire county council, has found it necessary to write to the chairmen of the different bodies who were called into conference and to point out that the county council has not at present any detailed scheme before it and that the object of the conference was to find out whether the various sanitary authorities would be willing for the council to prepare a scheme and to submit it to them. In the same letter he informs those to whom he writes that Colonel Wilkinson, who so generously offered a site near Lichfield for the sanatorium, has now withdrawn his offer and placed a sum of £2400 at the disposal of the county council in lieu thereof The West Bromwich board of guardians has adopted a report in opposition to the scheme on the grounds that the erection and maintenance of the sanatorium would cost much more than was estimated. It also objects that the open-air treatment is at present largely experimental and that further developments might render it necessary to erect buildings quite different from those now contemplated. There were at present a number of excellent institutions near the sea and in other more favourable situations than could be found in Staffordshire where patients could be sent and skilfully treated for £1 7*s.* per week. Further, it points out that the board has recently provided wards for the special treatment of phthisis. And finally it states that a sanatorium has been provided for Worcestershire by voluntary efforts and that there does not appear to be any reason why Staffordshire should not provide one in a similar manner, since it is a much richer county than Worcestershire. At a meeting of the Stafford board of guardians a certain Major Johnson seems to have delivered himself of adverse sentiments with a more than martial boldness He told the board that Dr. G. Reid the county medical officer of health, was a mere theorist and knew nothing at all about the practice that had been adopted in various sanatoriums for the prevention or cure of consumption. Even in localities which were suitable sanatoriums had been failures and the idea of setting up open air treatment in a climate like that of Staffordshire was absurd. As to teaching persons anything about the treatment of the disease the patients would have a period of six weeks of discomfort and cold, and when they got home the first thing they would do, instead of carrying out the new system, would be to shut the doors and windows and to make themselves comfortable by warmth. Mr. Peach challenged Major Johnson's statements and in the end the whole question, together with the West Bromwich board's report, was sent to a special committee to report upon the same.

Dec. 29th, 1903.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Royal Infirmary.

AT the meeting of the infirmary board yesterday, it appeared that the chairman, Mr. John Thomson, had had a letter from Judge Parry "in reference to the practice of inquiring into the circumstances of patients." A committee has been appointed to go into the whole question of voluntary payments from in-patients and of investigating the circumstances of patients. The use and abuse of hospital charity is a very large and difficult question, so that the committee has plenty of matter to deal with.

Free Meals for School Children.

Whatever view may be taken of the free-meal question as a matter of political and social economy, there is not much doubt that thousands of poor children cordially welcome these "free imports" and are the better for them. During last year the Manchester school board supplied 140,000 free dinners, the cost of which has been met by subscriptions and by the proceeds from school concerts, jumble sales, and social parties organised by the teachers. Under feeding is one of the factors in the production of the stunted, weakly young men and girls characteristic of the working classes of our manufacturing towns, and these meals are good so far as they go It is said that there is not much abuse of this charity, as all the cases are examined by the teachers and officers, and, moreover, it has always been found "that when distress diminished and the unskilled labourer found work again the demand for dinners diminished." Just now the city is pervaded by the Christmas spirit and though there is plenty of merry-making and social enjoyment among the well-to-do the abundant and widespread charitable work carried on with method and energy must do much to mitigate, for a time at all events, the increase of misery and privation that accompanies winter weather.

A Batch of Inquests.

Yesterday week five somewhat remarkable cases were inquired into by Mr. E. A. Gibson, the city coroner. The first was that of a soldier on furlough suffering from "a lump in the neck," apparently caused by a bad tooth, and an operation was necessary. Ether was used as an anæsthetic but he took it badly and before the operation was completed "he stopped breathing and artificial respiration was tried without avail." The next case was that of a girl, four years old, whose mother gave her a dose of saffron and whisky as she had been unwell. A tumbler half full of whisky was left on the table and the child got hold of it and drank the contents, dying the next day. The third case was one of hanging. In the fourth case a man bought "enough laudanum to kill five men" in the middle of the week and on the Saturday was found dead. It was supposed that he had taken it as the bottle was found empty, but no traces of the drug could be discovered post mortem and the medical attendant attributed the death to alcoholic poisoning. The next was that of a labourer who went into the engine room of some works "presumably" to dip a piece of cotton waste in some oil that had dropped from the engine. He became entangled in the machinery and was so terribly injured that he died after being taken to the Ancoats Hospital. A wire guard fenced the engine and he must have opened the door of it, though such action is forbidden by the rules.

Danger of Unprotected Fires.

We do not realise as we should the danger to child life, more especially among the poor, from the absence of fire-guards to the open grates almost always to be found in cottages. About a fortnight since Mr. Brighouse, the coroner for South-west Lancashire, spoke strongly on the subject at an inquest at Warrington on the case of a little girl, aged four years, who was burnt to death during the temporary absence of her mother. He stated that in the last three months he had had 11 similar cases and said it was useless talking to parents—that the only remedy was legislation. This was endorsed by the jury who added a rider to their verdict "that legislative action was necessary to make fire-guards compulsory."

Cremation in Manchester.

Although the prejudice against cremation is gradually breaking down and the mention of it does not now excite the horror often expressed in the early days of its revival, the Manchester Crematorium Company do not find their business increasing very rapidly. According to the report which was adopted at the recent annual meeting the crematorium pays its way but not very much more. The chairman expressed disappointment that they could not record any material increase notwithstanding the interest taken in the institution as evidenced by the income received from curious visitors, and he seemed to think it strange that "the gloomy impression created by the appearance of city churchyards" should not cause a "desire to have the remains of their dead reduced in a little over an hour into a pure white ash instead of leaving them to moulder for years in the ground, a source of danger to the living" They hope to transfer the crematorium to the corporation when public opinion has sufficiently ripened to make it possible. Cremation, with reason on its side, will have a hard fight before it vanquishes custom and sentiment.

Disused Mining Shafts.

The tragedy occurring recently at Hanley where a man walking along the street suddenly disappeared down the shaft of a disused mine from the rotten cover breaking through has given food for thought over wide districts in Lancashire There can be no doubt that in many of the villages, now grown into towns, there are forgotten shafts, covered with wooden beams over which earth has been thrown, that are dangerous death traps The stoutest timber under such conditions gradually becomes rotten In some places in Lancashire steps are already being taken to learn the position of these old shafts and to make them safe The Potteries are said to be honeycombed with old workings and the same applies to some districts in Lancashire

IRELAND

(FROM OUR OWN CORRESPONDENTS)

The Tenement Houses of Dublin

THE special correspondent of THE LANCET who came over here some years ago to report on the public health of Dublin furnished a startling and very unfavourable story of the condition of the tenement houses and slums of the city of Dublin It has not been forgotten, for his Excellency the Lord Lieutenant recently expressed a wish to visit those houses and to see for himself how things really are He was accompanied by the President of the Royal College of Surgeons in Ireland, who is chairman of the Association for the Housing of the Very Poor, and his first tour began on the afternoon of Dec 18th, when he commenced to traverse the streets and to visit the houses in the poorest parts of the south side of the city He went about incognito—in a cab—and left presents in the shape of Christmas hampers for those who seemed most destitute of food suitable for the festive season The Countess Dudley did the same thing in the northern poverty stricken districts and the Christmas presents which she distributed were kindly given by her own hands The Irish poor—dirty as they are—can still appreciate such delicate acts of kindness

The New Royal College of Science for Dublin

Mr Chenevix Trench, the arbitrator appointed under the Public Offices (Ireland) Act of last session, commenced to sit in the Four Courts, Dublin on Dec. 14th to hear the claims for compensation in respect of lands and premises on the west side of Upper Merrion street, which it is proposed to acquire by the Commissioner of Public Works under the compulsory powers of the above Act as a site for the new College of Science and extension of the offices of the Department of Agriculture and Technical Instruction The persons whose claims for compensation are now being dealt with are all medical men in practice in Dublin and the result of the arbitration is naturally a subject of interest to the profession here The claims which they make for compensation vary from £7000 to £3000 and the court has been occupied in hearing evidence as to the value of their houses and premises since it began to sit Each of them was represented by senior counsel, while the Attorney-General M P, and Solicitor General, M P, instructed by the solicitor of the Board of Works, appeared for the Crown The gardens connected with those premises in Merrion street are unusually long each house including a ground area of 100 yards from back to front. The space of ground which the Government is about to acquire by Act of Parliament measures therefore about 100 yards square and is situated in the best and most healthy part of Dublin

Dr Steevens' Hospital, Dublin

At a meeting of the governors of Dr Steevens Hospital held on Dec 21st Dr Robert L Swan was coopted a governor, Dr T Percy Kirkpatrick was appointed physician, and Dr Henry Jellett was appointed gynæcologist

Medical Events in 1903

The past year will mainly be memorable for the great growth of the Irish Medical Association and for the determined stand made by the Poor law medical officers to improve their present wretched position. The Irish Medical Association has not only greatly increased in numbers but new branches have been established all over the country and it has also converted it [illegible] so that medical men [illegible] of some of the exist [illegible] very likely resign their connexion with such organisations as the Irish association will do all in this direction—medical defence—that may be required The other special event in the medical history of Ireland in 1903 was the King's visit and the opening of the new Royal Victoria Hospital, Belfast, an institution which is constructed on lines altogether unique and peculiar and which will probably form the forerunner of future types of hospitals The working of the hospital is in every respect admirable The Royal Commission on Irish University Education has led to nothing

The New Maternity Hospital, Belfast

The governors of the old Lying in Charity have purchased a new site in a populous part of the city—namely, at the corner of Townsend street—where they propose shortly to begin the erection of a new thoroughly up to date maternity hospital which will be of the utmost advantage to the students of the Belfast medical school

The Treatment of Tuberculosis

On Dec 28th two of the Local Government Board inspectors (Mr R Agnew and Dr E C Bigger) held an inquiry in the union workhouse, Belfast, as to the proposed establishment of a sanatorium by the guardians at Whiteabbey, on the north west side of Belfast Lough The senior medical officer (Mr Robert Hall) of the Belfast workhouse gave evidence, as did the master, showing the congested state of that institution Four years ago they had 85 tuberculous patients, now (Dec 28th) they had 255 The air space in the union hospital was utterly insufficient The total space available was 586 800 cubic feet, of this 192 800 cubic feet were required for surgical cases which left 394,000 for the remaining patients, which was 48 600 cubic feet short of the required accommodation, calculated at the lowest scale of 600 cubic feet per head, and of these patients 255 were tuberculous The accommodation was altogether inefficient, being below what was known in any recognised hospital for such patients Apart from the fact that tuberculous cases needed special treatment they were dangerous to other patients and their removal would give accommodation as per scale for twice their number of the healthy The union hospital was at present overcrowded, and the premises known as the Abbey—Whiteabbey—capable of accommodating 60 patients six nurses, a resident medical officer, and superintendent—which he had inspected, were considered by Mr Hall to be suitable He believed the statement that there were 4000 consumptives in Belfast was a low estimate Further evidence having been given in support of the scheme some opposition was offered by local residents and Mr H C Manley dispensary medical officer of the district in which the proposed sanatorium is to be located in his evidence objected to the place selected as not being suitable on the grounds that the soil was cold and damp, the site was too low and too close to the village of Whiteabbey, it was exposed to east winds the air was relaxing, and there was local prevalence of pulmonary tuberculosis (of the total number of deaths registered in his district this year—96—there were 50 from chest diseases) The inquiry stands adjourned until Jan 18th

Dec 29th 1903

PARIS

(FROM OUR OWN CORRESPONDENT)

Renal Opotherapy in Albuminuria

At the meeting of the Academy of Medicine which was held on Dec 22nd a sensational communication was made by Professor Renaut of Lyons which affords grounds for thinking that many cases of albuminuria will in future be curable The following are the conclusions which Professor Renaut has drawn from his researches Extract of macerated kidney administered to patients suffering from renal insufficiency is one of the most active and most efficacious methods of medication hitherto employed It restores the function of a waterlogged kidney more than does any other [illegible] even in cases [illegible] s by the appli- [illegible] tit has been tried The extract has a powerful diuretic action and when employed for a reasonable space of time it brings up the urinary output to the normal and maintains it at that level Further, it has no harmful influence upon the affected kidney. Among other advantages of this method of treatment it rapidly reduces the output of albumin by the kidney owing to its renewing the activity of the gland. It will even cause a disappearance of the albumin for a long period and so there is every chance that, the tubules of the kidney being given functional rest, the renal epithelium will be renewed, at least in those cases, which are fairly frequent, in which such renewal is histologically possible. It is therefore, as Raphael Dubois discovered and demonstrated at one stroke, an antitoxic method of the first class. The antitoxin consists of the "preproducts" of the glandular secretion of the epithelial cells of the convoluted tubules and the important point ascertained by Dubois was that this antitoxin is not destroyed by the gastric juice. It is this fact which allows of the application of renal opotherapy. The kidney extract introduced into the organism per os exercises a real antitoxic effect On the other hand, signs of slight poisoning may arise from its use such as pruritus, urticaria, miliary rashes, sweats, or, after it has been administered for a few days, slight gastric disturbance. Apart from these complications, however, Professor Renaut and his assistants have never seen any unpleasant effects due to the use of the extract. It produces its antidotal effect in a regular and progressive fashion, and under its use the arterial hypertension, Traube's "gallop rhythm," and the tendency of the heart towards a fatal passive dilatation successively diminish, provided that the extract be given for a sufficient period of time. This method of treatment should be begun at as early a stage of the disease as possible and it should not be substituted for other therapeutic measures but used as an adjunct to them. Its only inconvenience is the necessity of preparing the extract fresh every day. But this difficulty can be easily surmounted if it be considered that the object of the treatment is to save human life.

Total or Partial Hysterectomy for Uterine Fibroids.

At a recent meeting of the Society of Surgery M Monprofit read a paper on the above subject. For himself he said that he was an advocate for total hysterectomy, as this operation had always been more successful in his hands than a partial operation and in the great majority of cases it offered no difficulty. He allowed, however, that when the patient was very feeble a partial operation was preferable for it took a much shorter time to perform. Myomectomy or simple removal of the ovaries also affects fibroids favourably. M. Pozzi was of a contrary opinion and considered that the partial operation was the operation of election, for it was more rapid and far less severe than a total removal He said that total hysterectomy gave a mortality of 9 per 1000, while for partial hysterectomy the proportion fell to 4 per 1000 He also drew the attention of the society to his method of operating. Instead of dividing the neck of the uterus transversely, destroying what was left of the mucous membrane with the thermo cautery and then closing the peritoneum over the stump, he prefers to make a wedge-shaped cut in the pedicle. The two sides are then brought together and the mucous membrane is thus inclosed by thick tissues. The peritoneal cavity is then accurately closed and is protected from all infection M. Rouvier did not approve of this modification but preferred a simple transverse section. The mucous membrane was then buried by sutures in the stump and the peritoneum was closed. Three other surgeons—M. Quénu, M. Schwartz, and M. Ricard—said that they considered that the question as to whether partial or total hysterectomy were the better might be considered as closed. In their opinion the total operation was no more *risky than the partial.*

A Healthy Parish.

During the week Nov. 29th–Dec. 5th of 1903 the parish (*quartier*) of St. Thomas Aquinas with a population of 26,116 persons had not a single death. During the same period the parish of Père Lachaise with a population of 51,832 had 31 deaths. In the latter parish there are only 15 medical men, or 1 to every 3000 inhabitants, while the former parish has 125 medical men, being about 1 for every 200 inhabitants. It must be remembered that the parish of St. Thomas Aquinas is a rich one and is nearly empty during the summer and autumn, all its inhabitants being at the seaside or in the country. It is therefore obvious that its 125 medical men have much less work than they would like.

A New Hospital.

M. Ambroise Rendu has just laid before the municipal council of Paris a plan for a new hospital for Parisians at Montmorency. Last year the municipal council decided on great schemes of hospital improvement and extension towards which it allocated a sum of some 40,000,000 francs. The chief object was to free the Paris hospitals from a crush of patients and to provide for those suffering from tuberculosis. In many of the hospitals tuberculous patients make up half the whole number treated and even at the Hôtel Dieu they form more than a third of the total number of patients. If, then, these tuberculous patients could be treated elsewhere the hospitals would have ample room for other patients. M. Rendu proposes that they should be treated at Montmorency on a site of 126,000 square metres which belongs to the Duc de Talleyrand-Périgord. On this site could be built a hospital containing 1000 beds, the patients being housed in separate blocks. The duke asks 825,000 francs for the site. The hospital will be reserved exclusively for Parisians and no clinical teaching will be given.

Dec. 28th, 1903.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Koch's Birthday.

ON the occasion of the sixtieth anniversary of the birthday of Professor Koch the *Deutsche Medicinische Wochenschrift* has issued a Festival Number to which the leading bacteriologists of Europe have contributed. It commences with an article on Professor Koch's Life and Work by Professor Löffler of Greifswald, dealing especially with his researches on tuberculosis, cholera, malaria, rinderpest, and other diseases of microbic origin. Professor Metchnikoff and Professor Roux of Paris contribute an article on the Experimental Production of Syphilis in Anthropoid Apes. They have succeeded in infecting a female chimpanzee with syphilitic virus, a chancre developing about 25 days after the inoculation. A month later a squamous exanthema appeared on the thigh, the back, and the abdomen and disappeared after four weeks. The animal unfortunately died about 14 weeks after the infection from general pneumococcic invasion. Some of the discharge from the chancre having been inoculated into the penis and the thigh of another chimpanzee, the result was that chancres appeared in both places, together with a general swelling of the lymphatic glands. No secondary symptoms ensued; the chancre on the thigh healed but that on the penis persisted till the death of the animal which happened about 45 days after the development of the syphilitic symptoms. No symptoms of syphilis were found at the necropsy; the death was attributable to infection by a kind of influenza bacillus which was found in the internal organs. The next article of the series is written by Professor Ronald Ross, of the Liverpool School of Tropical Medicine, and deals with Professor Koch's work on malaria, with especial reference to his determination of the frequency of malaria in children and his proposals to immunise the entire population of a malaria district by the systematic administration of quinine. Professor Ross does not hesitate to claim for Professor Koch a high degree of merit in this question, especially against the pretensions of certain Italian *savants*. Professor A. Celli and Dr. de Blasi of the Hygienic Institute of Rome contribute a paper on the possibility of separating the toxic principle of rabies by filtration. A diluted extract of the brain and spinal cord of affected animals was passed through a Berkefeld filter with the help of an exhaust pump at the temperature of the room and from 0·25 to 0 5 cubic centimetre of the filtrate was injected into the dura mater of dogs and rabbits. Of 23 rabbits only three survived and of four dogs all died. Of the 20 rabbits five died in from 14 to 40 days with symptoms of emaciation and paralysis. An emulsion of the medulla of these rabbits was accordingly injected into another series of rabbits, the results being that of 12 animals 10 died; of a third series of 12, 10 died, but only a few had symptoms of paralytic rabies. The four dogs died in from 19 to 88 days, showing general emaciation and depression. The necropsy of the deceased animals gave a negative result. Professor Paltauf of Vienna has written on agglutinins and precipitins and Professor Tavel of Berne on polyvalent antistreptococcic serum. Dr. Friedmann of the Anatomical and Biological Institute of Berlin University reports that the tubercle bacillus of the tortoise is very like the tubercle bacillus of the human species; by injections of the former bacillus he has succeeded in immunising guinea-pigs against tuberculosis. Other contributions to the Festival Number relate to the use of antidiphtheritic serum in general practice and to the cure of a case of puerperal septicæmia by injections of antistreptococcic serum. Lord Lister, who was also asked to contribute, has written the following letter to the editor: "I greatly regret that in consequence of the state of my health at present it is impossible for me to comply with your request that I should contribute to your Festival Number an expression of my high appreciation of the important labours of Robert Koch. No one, perhaps, has a greater admiration of his work than myself." Professor Koch happens to be spending his birthday at a great distance from Berlin—namely, at Buluwayo, in South Africa, where for the second time he has been asked to advise the Colonial Government in its measures against rinderpest. He is not expected to arrive home before the month of March and the celebration of his birthday must thus be postponed till that date. His bust will be unveiled in the Institution for Infectious Diseases and a museum, showing the development of the study of bacteriology, will be opened after his return. As Professor Koch is firmly opposed to a public celebration, only his present and former assistants will take part in the proceedings.

Dec. 28th, 1903.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Character of Present Immigration.

THE total number of immigrants last year was 857,046, the largest number in one year in the history of the country. In a recent report the United States Commissioner of Immigration states that the great bulk of the present immigration proceeds from Italy, Austria, and Russia, and from some of the most undesirable sources of population of those countries. Immigration from such countries as Germany and the British Isles has fallen to a very low figure. The great bulk of the present immigration settles in four of [illegible] he large cities of those [illegible] pouring into our cities, [illegible] o wanted because they are neither physically nor mentally fitted to go to these undeveloped parts of the country and to do as did early settlers from northern Europe. The number of immigrants from northern and western Europe last year was 203,008, or 28·8 per cent., and from southern and eastern Europe 610,813, or 71·3 per cent. These figures show that while there has been some increase in the immigration from northern and western Europe the greater proportion of immigrants has come from the less desirable races of southern and eastern Europe. The illiteracy of races as shown by the tests applied to immigrants over 14 years of age was as follows: western Europe 3·9 per cent., and for eastern Europe, including Spain and Portugal, 39·7 per cent. The Commissioner at New York states that there is a large body of immigrants who are not reached by our restrictive laws and who are undesirable because unintelligent, of low vitality, of poor physique, able to perform only the cheapest kind of manual labour, desirous of settling almost exclusively in the cities, and by their competition tending to reduce the standard of living of the American wage-worker and unfitted, mentally and morally, for good citizenship. He believes that at least 200,000, and probably more, aliens come here who will prove a detriment. It is misleading to assert that because immigration in the past has been a source of greatness to the country it should not be further restricted; past immigration was good, because most of it was of the right kind and went to the right place.

Pure Food Standard.

The Secretary of the Interior has approved and proclaimed the official food standards which have been formulated by the United States Food Standard Commission and the executive committee of the National Association of Pure Food Commissions. The object of the law is to establish standards corresponding to American food materials, whether raw or manufactured, and in accordance with the results of American processes of manufacture. The standards consist of definitions and chemical limits and embrace meat and its products, milk and its products, sugar and related substances, spices, and cocoa and cocoa products. No chemical limits are named for the meat products, the standard being fixed by definition only, which gives this description: sound, dressed, and properly prepared edible parts of animals in good health at the time of slaughter. The standard of milk is fixed at not less than 12 per cent. of total solids, not less than 8½ per cent. of solids not fat, and not less than 3½ per cent. of milk fat. The standard of condensed milk contains not less than 28 per cent. of milk solids, of which one-fourth must be milk fat. The standard of butter contains not less than 82½ per cent. of butter fat and may contain additional colouring matter. For cheese a minimum of 50 per cent. of butter fat in the water-free substance is prescribed. Ice-cream, to be standard, must have a minimum of 6 per cent. milk fat. Refinery syrups as ordinarily made are classified as molasses and syrups; the standard of the former requires not over 25 per cent. of water and of the latter not over 30 per cent. of water or 2½ per cent. of ash. These are examples of the work of the commission as far as it has fixed standards. The work is to be continued until the list of foods is completed. An exhibit of the work of the State Food Department is to be made at the World's Fair at St. Louis and an exposition of the methods of adulteration in foods and beverages is to be given in order to show the public how to protect itself in the purchase of food commodities.

A National Hygienic Laboratory.

The creation of this laboratory by an Act of Congress is a striking proof of the great advance of State medicine in the United States. The building, which is now nearly completed, is a model of its kind. It is located on grounds formerly belonging to the Naval Museum of Hygiene at Washington and will be under the direction of the Department of the United States Public Health and Marine Hospital Service. The building is constructed so as to give ample accommodation to the several branches of work, as chemistry, pharmacology, pathology, and bacteriology. The Act of Congress provided that there should be an advisory board for the hygienic laboratory, consisting of three competent experts detailed from the army, the navy, and the Bureau of Animal Industry, together with the director of the laboratory and five additional members appointed by the Surgeon-General of the Public Health and Marine Hospital Service, who shall be skilled in laboratory work in its relation to the public health. The chiefs of divisions are to be skilled in their respective lines of scientific research work, especially in its relation to the public health. The results of the researches of the laboratory are to be published in bulletins. The laboratory will be ready for occupation about the 1st of the new year and plans are now under way for the production of a standard diphtheritic antitoxin for distribution to manufacturers, those engaged in research work, and others. The Act of Congress referred to also placed the supervision of plants manufacturing these products under the Public Health and Marine Hospital Service. The examination of these products will be conducted in the hygienic laboratory. The result of this supervision will, it is believed, relieve the market of the spurious antitoxins.

Tuberculosis Congresses.

The number of congresses for the suppression of tuberculosis which have been, and are being, arranged to take place during the coming season is surprising. There is to be the Baltimore Tuberculosis Exhibition, to be held in January under the combined auspices of the Tuberculosis Commission, the Maryland Board of Health, and the Maryland Public Health Association. Another tuberculosis exhibition will be held in St. Louis in connexion with the exhibition of Social Economy and under the subsection of Hygiene. It is announced that a congress on tuberculosis, under the name of "International Congress on Tuberculosis," will be held in St. Louis in October. Again, there is the American Congress on Tuberculosis for the Prevention of Consumption, which proposes an international convention at Washington in April, 1905. These instances of proposed meetings for the consideration of the single subject of tuberculosis are but few of the occasions on which this all-absorbing theme is discussed. Unfortunately many of these congresses in this country are not of a character to command the sympathy and support of the leading men of the profession. While they do not specially do harm to the great movement now taking place all over the world against the great "white plague" they do not result in any very material advance in the adoption of radical measures for the extermination of this disease.

State Regulation of Marriage.

The Iowa Society for the Suppression of Disease and Degeneracy has prepared a Bill to be submitted to the legislature of that State providing that before a marriage licence can be issued to any person in that State a physician's certificate of examination must be obtained showing that the said person is physically and mentally qualified to enter into the married state under the laws of that State. The State of Iowa has long been in the front rank as regards sanitary, social, and political reforms and this new departure will be watched with great interest.

The Administrative Control of Tuberculosis.

The health authorities of New York passed an ordinance in 1897 requiring the registration of every person suffering from pulmonary tuberculosis by the physicians, managers of institutions, hospitals, and dispensaries of the city. Stringent regulations were made in regard to the management of all reported cases and being printed on cards were furnished to patients, friends, and guardians. The report of the results has just been issued and forms an interesting chapter on the value of the administrative control of contagious and infectious diseases. The death-rate from pulmonary tuberculosis had steadily fallen during the period.

Dec. 20th, 1903.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the first professional examination for the diploma of Fellow at the half-yearly meeting of the examiners :—

Oswald Lacy Addison, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., University College and K [illegible] ames Alford Andrews, M.R.C.S. Eng., I [illegible] Camb., Cambridge University and Guy' [illegible] Ball, George Norton Bartlett, Thomas Henry Barton, and George Cockcroft, Guy's Hospital; Robert Tullis Baillie, M.B., Ch.B. Edin., Edinburgh [illegible]ey Blundell Bankart, B.A. Camb., Cam- [illegible] College, and Guy's Hospital; Robert [illegible] Cambridge University and Guy's Hos- [illegible]ring Cross Hospital; Bertram Thomas Johnson Glover, Liverpool University; Paul Leon Guiseppi, St. Bartholomew's Hospital; William Hackney, M.R.C.S. Eng., L.R.C.P. Lond., M.D. Toronto, Toronto University and King's College, London; Arthur Herbert Hart, M.R.C.S. Eng., L.R.C.P. Lond., M.S., M.D. Durh., Durham University and the London Hospital; James Willie Heslop, M.R.C.S. Eng., L.R.C.P. Lond., M.B., B.S. Durh., Durham University; Montague Leonard Hine, Middlesex Hospital; Arthur Cyril Hudson, M.A., M.B., B.C. Camb., Cambridge University and St. Thomas's Hospital; Thomas Bramley Layton, Guy's Hospital; James Edlington McDougall, M.R.C.S. Eng., M.B. Vict., D.P.H. Camb., Liverpool University; George Percival Mills, Birmingham University; James Eu [illegible]gh, Robert Foster Moore, B.A. Camb., Al [illegible] Samuel Shuttleworth Rendall, St. [illegible] Gerald Charles Frederick Robinson, Guy's Hospital; Henry Charles Samuel, King's College London; Charles Harold Smith and Clare Oswald Stallybrass, Liverpool University; Claude Edward Tangye, B.A. Lond., Birmingham University; Walter Welchman, B.A., Cape of Good Hope, Guy's Hospital; Harold Beckwith Whitehouse, St. Thomas's Hospital; and Courtenay Yorke, Liverpool University.

96 gentlemen presented themselves for this examination of whom 32 passed and 64 were referred.

Notes, Short Comments, and Answers to Correspondents.

THE RESIGNATIONS OF MEDICAL MEN AT OLDBURY ALKALI WORKS.

ONE of the medical men concerned sends us the following account of an extraordinary situation at Oldbury:—

> Seven medical men residing at Oldbury, Langley, &c., about five miles from Birmingham, have ceased their connexion with the Oldbury alkali works in the following circumstances. The works employ about 700 hands and for many years past it has been the custom to deduct from each employé the sum of 3*d.* a week for the medical man. The employé could select which medical man he liked from among the seven medical officers for a year, the medical man being paid according to the number of hands on his list. For this 3*d.* a week, or 13*s.* a year, he had to attend anyone at the works, from the highest salaried officials down to the navvy and their families, infants and adults, to conduct confinements, perform vaccinations, and make visits at their homes, whether he resided six yards away or six miles, whenever required, day or night. The medical man had also to find drugs and surgical appliances and, it is alleged, as will be seen, to provide the money for donations to benevolent institutions in addition. The medical men met together and asked that the whole of the money paid for their services by the men should be handed to them in its entirety, the reason for this being that from the 13*s.* per man the authorities have been in the habit of deducting 1*s.* 6*d.* to form a "Dispensary Fund," from which the cost of trusses, eye shades, crutches, &c., could be defrayed for the benefit of the men. 700 times 1*s.* 6*d.* make £52 10*s.*, and this substantial sum was deducted every year. It is, the medical men contend, absurd to suppose that anything like £52 10*s.* could be required for such purposes. It is alleged that from the surplus all donations to charitable institutions were made on behalf of the men. The request of the medical men was *refused.* A meeting was held consisting of Mr. A. M. Chance, a gentleman noted for his public benefactions, and his committee. The petitioners were informed that the medical men were sufficiently well paid and that no alteration in their present rate of payment would be considered. They were further informed (presumably as a punishment for daring to ask that they should not be robbed of one-eighth of their just dues) that three of them would be dismissed and that only the four who were at the top of [illegible] men would be allowed to act [illegible] *of them would be dismissed* [illegible] ed from elsewhere to do the work. The medical men refused to allow any of their number to be dismissed for the benefit of the rest, so the following notice was posted up in the works on Dec. 24th:—
>
> Dec. 24th, 1903.
>
> OLDBURY ALKALI WORKS PROVIDENT SOCIETY.
> DISPENSARY BRANCH.
>
> In consequence of the doctors having declined the offer and terms of the committee for their services next year this branch of the society will cease on Thursday next and after that date the deduction from the wages will cease.
>
> (Signed) A. M. CHANCE, Chairman.
> G. A. COTTERILL, Secretary.
>
> Then follow the names of the committee.

Our correspondent concludes by expressing a hope that the attempt to fill the vacant posts by importation from outside of any medical man will fail, and *we endorse this view on the strength of his* statement. We do not pretend to have tested it in detail, but he tells his story categorically, and no medical man should accept work under the Oldbury Alkali Works Provident Society until he has [illegible] Union, 610, Coventry-[illegible] ame of Chance is an [illegible] honoura[illegible] annot think the firm intend to treat professional gentlemen either with meanness or with discourtesy. Possibly neither side understands the arguments of the other.

FAILING TO NOTIFY CASES OF SMALL-POX.

AN unfortunate case in which a medical man was summoned for failing to notify cases of small-pox was dealt with recently at the Manchester police-court. On Sept. 30th the defendant notified that his servant had small-pox and she was taken to the hospital. He could not explain its origin and said that he had no suspicious cases passing through his hands at the time. In the course of a fortnight several cases occurred in the neighbourhood "and it appeared that [illegible] had been treated for more than a month" by [illegible] r. J. McR. Cowie, and [illegible] me cases of small-pox and chicken-pox had points of resemblance [illegible] experienced medical man should have any difficulty in diagnosing them. Mr. Brierley, the stipendiary, said that a person was only liable if he was aware that the cases were small-pox. The defendant said he had only been in practice 12 months and had not attended a case of small-pox, and in the case in question "he never dreamt of small-pox." He was summoned for four cases but only fined for one, the others being dismissed. A fine of £5 and costs was inflicted, the stipendiary remarking "that he could not believe that the doctor was unaware that his patients were suffering from small-pox." This case does not reflect much credit on the teaching which can allow so important a point as the diagnosis of small-pox and chicken-pox to be passed over without special attention. For some time before the recent recrudescence of small-pox set in the supply of cases for clinical teaching was scanty and it might well happen that a young practitioner had never seen a case. In the future, thanks to the conscientious objectors or passive resisters and the *laissez-faire* policy of our rulers, it is probable that the supply of small-pox cases will be quite sufficient for clinical purposes and no practitioner of 12 months' standing will be able to say that he has never seen a case.

A DUELLIST'S PRECAUTION.

A QUAINT recognition of one of the common causes of septic conditions in gunshot wounds occurs in the entertaining "breezy papers" recently edited by Sir Herbert Maxwell and published by Mr. John Murray. Nearly a century ago, in July, 1806, Mr. Creevy wrote to his friend, Dr. Currie: "You see, my friend, Mr. Howorth, has been adding to the amusements of Brighton races by fighting a duel with Lord Barrymore. His lordship was his adversary at whist and chose to tell him that something he said about the cards was 'false,' upon which Howorth gave him such a blow as makes the lord walk about at this moment with a black eye. Of course, a duel could not be prevented. When they got to the ground Howorth very coolly pulled off his coat and said, 'My lord, having been a surgeon I know that the most dangerous thing in a wound is having a piece of cloth shot into it, so I advise you to follow my example.' The peer, I believe, despised such low professional care and no harm happened to either of them." It might be suggested that "low professional care" carried to its logical conclusion would have recommended the angry card-players to fight naked; they adopted, however, a more effective precaution in not getting hit.

CIVIL WAR.

WE received last week, just as we were going to press, a long letter from a gentleman who signed himself, "Chairman of the National Canine Defence League." Somebody seems to have accused him of being inaccurate. As, however, we have made no allusion to him or to his work or his society's work we do not think his defence of his previous statements, which was not made in our columns, need appear in THE LANCET. Somebody else has sent us a notice of a statue that is being raised to a brown dog. This seems to us a very reasonable movement in spite of the inconceivable silliness of its promoters. It may do good that the public should be reminded of the amusing failure of the National Antivivisection Society in its efforts to blacken the character of physiologists. We cannot, however, arbitrate in the quarrels of rival antivivisection societies.

THE TREATMENT OF PEDICULI CAPITIS.

To the Editors of THE LANCET.

SIRS,—If your correspondent "E" will sponge the hair with dilute acetic acid, or even simple vinegar, I think he will attain his object. It will be wiser, however, to combine some parasiticide with it to ensure the destruction of any young brood and thus prevent the renewing of the nits.

I am, Sirs, yours faithfully,

Ryde, Dec. 30th, 1903. J. MILLER.

*** We have received several other replies advocating different preparations of turpentine or paraffin; notably one from from Messrs. Arthur and Co. recommending the steady use of paraffin, the head to be combed regularly, shampooed, and dried in the air.—ED. L.

THE KEARTON PHOTOGRAPHIC EXHIBITION.

Messrs. Richard and Cherry Kearton will show their collection of enlarged photographs, taken direct from nature, of birds, beasts, reptiles, insects, &c., at the Modern Gallery, 175, Bond-street, W. A private view will be held on Jan. 1st, 3 P.M. to 6 P.M., at the close of which Mr. Richard Kearton will deliver a lecture. The exhibition will be open from 10 A.M. to 9 30 P.M. from Jan. 2nd to Jan. 12th inclusive, except on the evenings of the 6th and 8th, when the exhibition will be closed at 6 P.M. We recommend every student of natural history to make an opportunity of seeing these photographs.

"THE DOCTOR."

WE have been asked to warn medical men, chemists, and others against buying, or in any way dealing with, pirated copies of the well-known picture called "The Doctor" by Mr. Luke Fildes, R.A., of which Messrs. Thomas Agnew and Sons, of 39B, Old Bond-street, publish an engraving. The picture has been extensively reproduced in America and from time to time pirated copies have been imported into the United Kingdom either as engravings or for use as advertisements, mainly in connexion with American chemical preparations. Large numbers of these copies have been seized and injunctions obtained against the importers. Electrotypes of the picture have also been offered to printers and chemists in the United Kingdom by several American electrotype manufacturing firms. It is desirable in the public interest that it should be as widely known as possible that the importation, exhibition, or use of any of these unlawful copies or electrotypes constitutes a breach of the Copyright Acts and that the owners of the copyright are compelled for their own protection to take proceedings against all persons whom they may find committing such breaches.

DIABETES.

To the Editors of THE LANCET.

SIRS,—Is it permissible to give maltine and its preparations to a patient suffering from diabetes mellitus, also glycerine? I have a patient attacked by this disease; since it came on he has lost his vision for near objects and cannot read or recognise faces a yard or two from him. Is there any special treatment for this loss of vision which I see mentioned in some works on diabetes? I shall be glad if any brother practitioner can advise me on the matter.

I am, Sirs, yours faithfully,

Dec. 22nd, 1903. TROUT.

IODIDE OF POTASSIUM AND SNEEZING.

To the Editors of THE LANCET.

SIRS,—The "excessive sneezing attended by severe nasal and conjunctival irritation" caused by small doses of iodide of potassium as described by "Cyclops" would probably disappear if larger doses of the iodide were given, say 10 or 15 grains. The action of the drug is also greatly improved by making the patient sip a tumblerful of hot water about an hour before meals. I am, Sirs, yours faithfully,

London Lock Hospital, Dec. 24th, 1903. J. S. PURDY, M.B. Aberd.

THE VAGINAL DOUCHE.

To the Editors of THE LANCET.

SIRS,—We must apologise to Dr. G. Crichton and acknowledge that he has much justification for his conclusions. Our catalogue shows 24 illustrations of vaginal pipes; of these, 18 are intended to show no hole at the apex; the remaining six are old illustrations, and we must admit misleading, but the pipes themselves are supplied without holes at the ends.

We are, Sirs, yours faithfully,

Dec. 29th, 1903. DOWN BROS., LTD.

◆

Dr. A. C. Ingle (Downing Grove, Cambridge) will be obliged if any of our readers can refer him to a firm who will prepare diagrams for lectures.

M. O. H. has omitted to furnish us with his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title page to Vol II of 1903 which was completed with the issue of Dec 26th, are given in this number of THE LANCET

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 will be ready shortly Bound in cloth, gilt lettered, price 18*s*, carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C , are dealt with by them ? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are .—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year .	£1 14 8
Six Months	0 16 3	Six Months ..	0 17 4
Three Months	0 8 2	Three Months ...	0 8 8

Subscriptions (which may commence at any time) are [illegible] Cheques and Post Office Orders (crossed [illegible] inster Branch") [illegible] CHARLES GOOD, [illegible] W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address— THE MANAGER THE LANCET OFFICES, 423 STRAND, LONDON ENGLAND

An Address

ON

HE FUTURE OF ELECTRO-THERAPEUSIS.

Delivered at the Annual Conversazione of the British Electro-Therapeutic Society on Dec. 18th, 1903,

Y SIR ISAMBARD OWEN, M A., M.D.CANTAB., F.R.C.P. LOND,
PHYSICIAN TO, AND LECTURER ON THE PRINCIPLES AND PRACTICE OF PHYSIC AT, ST. GEORGE'S HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—I have first to thank ou for the compliment you have paid me in inviting me to ddress you this evening. Next I have the pleasant task to erform of congratulating you upon the success that has ttended your efforts to establish this society and to place it n a substantial basis. I learned of its foundation with much nterest and satisfaction. It is in my opinion a society that vas greatly needed and one that has in its power to render mportant service to the cause of scientific medicine. The reatment of disease by physical methods, and in particular [illegible] liscovered forms of physical [illegible] n pushed forward of late years [illegible] remarkable claims have been nade in its behalf that the profession at large is greatly in eed of sober guidance and of a source of authoritative nformation in the matter. In the face of the eager xpectation and extravagant promise that certain of the nost recent developments of physical therapeutics have in nany quarters evoked it is very desirable that those nembers of our profession who are in a position to under- [illegible] investigation of the value of the new [illegible] together both to assert their position [illegible] professional brethren and by union of effort to strengthen the cause of serious and critical inquiry nto the matter. May I take it as an earnest of the critical pirit in which the association is approaching its task that you have invited to this desk to-night, not a professed specialist in electro-therapeutics or neural pathology, but a general physician whose field of work obliges him to take a [illegible] h a matter and whose personal [illegible] that of being somewhat unduly [illegible] therapeutic results.

Your society will, I think, need an ample measure of the critical—may I say even of the sceptical—spirit in its self- mposed task of dealing with some of the physico-therapeutic questions that are now agitating the medical world, for the atmosphere in which your work will have to be done is one that may best be described as oppositely charged. The many unexpected revelations which physical science has yielded [illegible] years have prepared the public mind [illegible] f physical marvels and whetted its [illegible] The report of each new departure [illegible] falls nowadays on eager ears, both within and without the medical profession. As each fresh discovery in the realm of pure physics is followed by its [illegible] treatment the news is speedily flashed [illegible] atever region it reaches it is sure to [illegible] body of adventurous spirits eager to [illegible] working the new field of therapeutic [illegible] em. Our therapeutic pioneers for the most part, let me frankly grant, are genuine and honest enthusiasts; but a large element among them is none the less, if one may judge from its published utterances, as little fitted to deal with a question of scientific therapeutics as the followers of Walter the Penniless were to undertake the siege of Jerusalem. To complicate the situation further, these questions are not always left entirely in the hands of members of our own profession. The movements of the regular troops are perturbed by those of the camp followers who are claiming to take a place in the fighting line. Members of various occupations remotely connected with medicine, ignorant alike of pathology and diagnosis, affect to take an active share in directing medical treatment and find their pretension admitted seemingly on the paradoxical ground that their sole armamentarium is a piece of powerful physical apparatus, wielding forces as yet but imperfectly measured or understood. Need we be surprised in the circumstances at the premature tales of wonder that occasionally reach our ears or at the roseate hues in which we find the future of terrestrial medicine painted? "*Redeunt Saturnia regna*." The age of miracles is to be restored. Cancer is to be reft of its sting, gout and rheumatism to cease from troubling, the tuberculous are to be healed, the osteo-arthritic to rise up and walk; all that is needed is for the sufferers to place themselves, like Rider Haggard's "She," in the path of the latest discovered form of radiant energy. The art of medicine is reduced to a degree of simplicity that Sangrado himself could scarce have improved on. To sift in such cases the grains of sober fact from the chaff in which they are buried is, I understand, a part of the work which your society has proposed to itself, and all honour to you for undertaking it. Difficult and even invidious as the task must needs be it is one of urgent necessity, for unless the two are separated a wind threatens ere long to arise that will carry both wheat and chaff indiscriminately away. To a period of exaggerated expectations one of equally groundless distrust must inevitably succeed. The popular idol whose day of unmerited favour is past is liable to become the victim of equally needless opprobrium, and it may be long before a hearing can be obtained for a calm and impartial judgment. It is to your society and to societies of like aim that we shall have to look to save the solid work that is being done in these matters from discredit and to incorporate it finally in the growing fabric of accepted medicine.

No philosopher, as far as I know, has ever yet thought of making inquiry into that most suggestive subject, the psychology of therapeutic belief and therapeutic error. Few philosophers, it is true, have the necessary experience of medical practice and few practising medical men have the necessary leisure for philosophic meditation. Were a philosopher with the requisite experience of medicine to arise I should incontinently urge him to render his profession this service. The results, I feel sure, would be of practical no less than of theoretical value. Generation after generation we find ourselves, or perhaps I ought to say we find our neighbours, straying into the same fallacies of observation and reasoning on therapeutic questions without taking heed of the warning that the admitted mistakes of our forefathers should give us. How else can we explain the meteoric series of new remedies and improved modes of treatment that whirl periodically into the therapeutic sky and blaze for a term of years in the lustre of a reputation that seems to be amply guaranteed only in the end to sink silently into oblivion and to be heard of no more? One by one, it is true, genuine advances in therapeutics are being made; one by one remedies for disease of unquestioned efficacy are added permanently to our store, but their volume compares ill with the mass of once popular specifics that now lie as discarded litter along the path that scientific medicine has laboriously travelled.

In view of this ordinary phenomenon of medical history I do not think you will regard me as displaying an unconscionable degree of scepticism in surmising that a large part of the recent literature of certain electro-therapeutic methods will eventually share the common fate and be left derelict on the roadside in its turn. While awaiting the advent of our imaginary teacher may I so far usurp his rôle as to [illegible] suggest that while [illegible] we have recently [illegible] sophic successors [illegible] will be ascribed by them to imperfect calculation of prognosis in the individual case? May I venture to surmise that our medical Socrates will claim to have reduced a part of our alleged curative results to the mere natural termination of transitory functional disorders, a part to the psychical relief of symptoms mainly of psychical origin, and yet another part to the natural pauses or fluctuations in the march of organic diseases which, like most forms of pulmonary tubercle for example, normally tend to run a remittent or intermittent course—that, in fine, he will find a large number of plausible therapeutic conclusions to have been arrived at either by the common error of neglecting comparative methods of investigation or by the equally fatal habit of drawing deductions from minor premisses without taking the trouble to verify the accuracy or even to define the terms of the major?

But when destructive criticism has done its worst and all that it can reasonably challenge is left out of the account, the body of established fact which recent electro-therapeusis can claim as her own will not, I undertake to say, appear either small or unimportant. If we limited our gaze to one department of electro-therapeutical work alone; if we even contended it had done nothing for certain outside this department; if it could be said to have shown no more than this: that in the various forms which radiant energy assumes we have a manageable means of modifying profoundly the vital processes of the individual cells; that in these modes of force we have, further, the power of checking, or of attenuating, or of rendering the tissues resistant to the invasion of certain parasitic organisms; and that these forces can be practically utilised for the effectual checking of such terrible maladies as lupus, epithelioma, and rodent ulcer;—putting the matter thus, I say, at its lowest conceivable estimate, we should have to allow that electro-therapeusis must be credited with one of the most remarkable steps in therapeutic knowledge that the present generation has seen.

But though we may single out this branch of electro-therapeutical work as being that in which its most assured successes have been won, solid advance has beyond doubt been made in many directions besides. Less conclusive, perhaps, we must admit the results in some other departments as yet to be, but therein is no ground for discouragement. Electro therapeutic methods, we must remember, are still in their infancy and though in other branches of work it may not as yet be possible to adduce equally complete chains of proof we may well be satisfied for the present to see a body of presumptive evidence steadily growing and to recognise hopeful signs of what future years may bring forth. Hardly though we may credit the effects, at times alleged to have been obtained, of radiant energy on deeply seated growths our knowledge of its penetrating powers justifies the conjecture that future improvements in apparatus may bring that, too, within the range of therapeutic possibilities. Though we must as yet suspend judgment on the curative effects claimed for induced vibrations in so suspiciously long a list of constitutional maladies the knowledge we already possess of their influence on the metabolic processes of the body forbids us altogether to dismiss the expectation that here, too, we may be really upon the track of therapeutic methods of the greatest value.

Nor can anyone fail to recognise, though fortunately it has so far eluded the eye of the sensation-monger, the extreme interest and promise of the important work that has already been done upon the subject of phoresis. Phoresis as a means of treatment is as yet in its earliest experimental stage but the possibilities that lie hidden in it seem great. It is no unjustifiable hope that one day it will enable us to solve the standing difficulty of ordinary therapeutics and place in our possession the means of accumulating effective doses of powerful chemical or physiological remedies in those parts of the organism in which their action may be beneficial without the present necessity of diffusing them more or less equally through the fluid contents of the body and thereby inducing their effects on organs which they influence injuriously. How far these and many other tempting possibilities are likely to be fulfilled we shall look to your society from time to time to tell us.

Let us, moreover, not underestimate the value of electro-therapeutic work by omitting to take into account the unconscious influence it has exerted upon the course of contemporary physiological and pathological thought. If there have been times when the tendency of physiology and pathology has been too strongly towards a purely chemical explanation of their problems, recent electro-therapeutic work must be counted among the causes which have made for a fuller consideration of the part which physical forces play in the intimate life of the cell. By the patient, reserved, and critical study of your fascinating specialty, gentlemen, by the discountenance which a strong association such as this can show towards the elements of sensationalism and extravagance with which some parts of the subject have unfortunately been associated, you will, I feel sure, be able ere long to rescue the practice of it from the hands of pretenders and to place it in its desired position as an essential branch of medical therapeutics. It is time, I think, that the public learned to recognise the danger it is running in playing with the powerful physical agencies that are the subject of your investigations. That electric applications should, like the Turkish bath, be occasionally taken in harmless forms and degrees by healthy people, avowedly as luxuries, is natural and need not perhaps call for medical animadversion, but the public should be fully advised that if these physical agencies are used for serious therapeutic purposes they must be used in a serious manner and under serious responsibility by persons trained to understand the nature and the possibilities of the maladies they are treating as well as the mere construction of the apparatus employed, and that, like other serious remedies, these agencies may be sources of danger if administered by uninstructed or half-instructed persons.

The prospective importance of physical methods in treatment, as well as the importance of physical considerations in physiology and pathology, suggest one further question which I will venture, in conclusion, to commend to the attention of the association. Is the place at present assigned to the study of physics in the medical curriculum commensurate with the anticipated requirements of future medical practice? For myself I should unhesitatingly say no. Medicine has been so habituated to regard chemistry as its especial handmaid among the pure sciences that I think it has been a little blind to the rapid advance of physical investigations and to the bearing they have on its own field of work. The tendency has been, I fear, to treat physics rather as an appendage to chemistry than as the fundamental science on which chemical conceptions themselves are largely based. I am not, I admit, raising this question on purely utilitarian grounds. In the educational world I have repeatedly urged, and not always to unwilling ears, that any scientific education, to be worthy of the name, must needs begin with the study of mathematical physics. Difficult, we all know, it must be to find room for any fresh extension of scientific training in the crowded years of the student's career; but is there no unnecessary lumber yet included in the curriculum that could be jettisoned without practical loss to meet so important a claim? In the search for a countervailing remission of requirement I for one would be hardy enough to lay a sacrilegious hand on the sacred ark of anatomy itself. In the vast mass of minute anatomical detail that the ordinary student is caused to commit to memory, could there not be found, say, a poor ten per cent. of matter that the average medical practitioner would be none the worse off for never having been obliged to learn? But this, I fear, is too large a subject to discuss at the close of a brief address. I will merely add that for my own part I should esteem the average man neither the worse educated nor the less fitted for the treatment of ordinary disease if in his early days he had given a little more attention to the undulations of ether and a little less to the details of the sphenoid bone.

A Lecture

ON

STERILITY.

Delivered at the Medical Graduates' College and Polyclinic on Oct. 26th, 1903,

BY PETER HORROCKS, M.D., F.R.C P LOND.,

SENIOR OBSTETRIC PHYSICIAN TO GUY'S HOSPITAL.

GENTLEMEN,—When two people marry it is natural and healthy that they should desire to have children. Anything that militates against this consummation, if it be at all widespread in its operation, would lead to a diminution in the rate of progress in population and if continued for a few generations might result in the decadence of a nation. Fortunately, in this country at all events, there is no falling off in fertility and we are so numerous that we can afford to spare many thousands who emigrate every year. Still, it is a fact that, speaking broadly, about one marriage in ten remains childless.[1] Almost every practitioner is consulted sooner or later on account of sterility and therefore it is important that he should have as clear a knowledge as possible of the causes that may exist and of the remedies that are available. Now in the human species it is necessary for the successful production of a child that there should be: (1) a living ovum; (2) one or more living spermatozoa; (3) that these two should meet and coalesce; (4) that the meeting place should be a suitable one; (5) that the ovum after impregnation should anchor inside the uterine cavity; (6) that the human nest (endometrium) should be healthy; and (7) that there should be nothing to prevent the uterus from developing to term or at all events to such a time that the child is viable.

---

[1] Duncan: Sterility.

1. A Living Ovum.

The woman produces the egg. She begins to do this at puberty and she ceases at the climacteric. She produces an egg before she menstruates, as is evidenced by the fact that in India girls not seldom become pregnant before ever they have menstruated. Menstruation is looked upon by most physiologists as the parturition of an unimpregnated ovum. The human ovum has rarely, if ever, been seen in the unimpregnated state as it passes out of the uterus. For it is so microscopic, being not much larger than a white blood corpuscle. Hence one kno[illegible] movements, if any, when [illegible] has amœboid movements or [illegible] one may fairly say that an [illegible] dead spermatozoon, the lack of movements of which can be easily detected. I have seen patients where apparently no other conclusion could be come to than that they had only dead ova, although one could not prove it. That it is so sometimes is strongly supported by the fact that you may have certain seeds which are incapable of germinating in any soil, although indistinguishable from other seeds which will grow. When a woman menstruates regularly and moderately, when she has no discoverable defect or disease, when married life is carried out perfectly, and the spermatozoa are known to be potent, then should such a woman remain sterile during the years of greatest productivity—namely, from 25 to 37—one can say that it may have been that the ova or eggs were dead. Of course, they might be alive and yet could not be fertilised by that particular seed, for there are cases on record where a sterile marriage has been dissolved and each party has subsequently had children by a different wife and husband respectively.[2] Darwin proves this also in regard to certain animals. It would appear that the ova produced by a female during the first and last 12 years of menstrual life are not nearly so fertilisable as those produced during the middle period. Thus, a girl marrying any time between 13 and 25 years is not so likely to have children, or at all events as many children, as if married between 25 and 37 years; and between 37 and 49 years she is still less likely to have children. Not only so, but a woman who bears children, say, up to 37 years of age often remains sterile after that, although living under the same conditions of married life.

When the ovaries are not acting well the woman is apt to get fat. The relation between obesity and ovarian function is one of great interest. You know that after the climacteric a woman as a rule puts on flesh—she gets fat especially in the abdomen, so that she is what is called matronly. Many ladies strongly object to this natural obesity and will try to remedy it by various means, such as tight corsets, belts, and the like, but they are so uncomfortable that they are obliged to leave them off. If the ovaries are removed by operation the same increase in adipose tissue is noticed. Eunuchs are sleek and fat for a similar reason. Remove the testicles and a man gets fat. A capon is a cock chicken made fat by castration. Hence obesity, although not a cause of sterility, is often associated with it. The ovaries are not acting or are acting badly, no ova are being produced, or only few or only bad ones, and the sterility and obesity are due to the same cause. Hence, speaking generally, a fat girl is less likely to conceive than a thin one. No doubt you all know instances of fat women who are fertile. Probably in such cases the obesity has no relation to ovarian inactivity. Food seems to have a good deal to do with the fertilisability of the ova. It is a well-established fact that poor folks have more children as a rule than rich folks When a woman has rich food and as much of it as she likes, when she lives well every day of her life and perhaps takes wine, when she does no work and perhaps but little play in the way of physical exercise, her chances of motherhood are less and the average number of children she produces is less than in the case of a hard-working woman who perhaps not seldom has barely enough to eat and what she does get is simple plain fare which her richer sister could not eat.

The same is true of animals, and it is an interesting point in this connexion that many wild animals, especially of the nobler species, never breed whilst in captivity, as if in their wild state they were able to obtain certain food which they never get in captivity and which enables them to breed. They may lose all sexual desire and refuse to cohabit or they may cohabit freely and yet remain sterile. Anæmia or plethora, nerve conditions [illegible] choly), alcoholism, and dr[illegible] probably through interfer[illegible] proper maturation of the ova Interbreeding, too, may act in the same way. Certainly it is a well-known cause of sterility. An heiress is often sterile, particularly when she inherits her wealth through being an only child. The race is dying out through some factor acting on generation after generation. And interbreeding is one such factor. Hybridity causes sterility for the same reason, though the male is more frequently affected than the female, in animals at least.

2. One or More Living Spermatozoa.

It [illegible] For [illegible] by [illegible] always the case and certainly no one would assert that more than two or three ever penetrate a particular ovum. And yet when you consider how many thousands exist in the semen ejaculated in one emission you will realise how bountifully nature provides. It is the same throughout the animal and vegetable kingdoms.

When marriage proves sterile the husband generally assumes that it is his wife's fault. And as a rule she meekly accepts this spoken or tacit verdict and will frequently weep in secret and will sometimes get depressed and melancholy, feeling that she is not able to satisfy her husband's wish and that there is something lacking in her that other women possess. But as a fact the male is at fault in about one in ten cases, so that if you find after careful investigation that there is no discoverable cause for sterility in the wife you must then turn your attention to the husband. You may discover that his semen contains no spermatozoa at all or only a few feeble ones or only dead ones. Very likely in such a case he may not know that there is anything at all the matter with him. In some cases, however, you will find a cause of absolute sterility in the male, for example a congenital defect, and as a rule the husband knows in such a case that he is at fault. Sometimes he refuses to be examined and when he does so you may be pretty sure that he has a reason for it.

3 That these Two should Meet and Coalesce.

Probably 99 per cent of all cases of sterility are due to something which prevents the ovum and spermatozoon from meeting. In a healthy condition the ovum maturates in the [illegible] makes its way down the Fallopian tube and into the uterine cavity, where it sojourns for a time and if not impregnated it passes out with the menses and is lost. If impregnated it is thought by some that in a normal condition the fertilisation—that is, the penetration of the ovum by the spermatozoon—takes place within the Fallopian tube, and that may be the case; but in all probability normal fertilisation takes place also within the uterine cavity. Certainly we know from pathological conditions that fertilisation may take place with the ovum still in the Graafian follicle (ovarian ectopic gestation), or in the peritoneal cavity (abdominal gestation), or within the Fallopian tube (tubal gestation). All these facts prove that the spermatozoa can and do travel up the uterine cavity and along the Fallopian tubes and into the peritoneal cavity and on to the ovaries and this fact is of the highest importance. There might be some condition which prevented the ova from reaching the uterine cavity, as, for example, a double salpingitis, leading to blocking of, say, the ostium abdominale of the Fallopian tube. The fimbriæ or tentacles get inflamed, swollen, shortened, and spoiled so that the ovum is no longer caught but falls into the peritoneal cavity or into the meshwork of inflammatory lymph thrown around the tube end. Nearly always both tubes are affected and the patient remains sterile for years. But in a few instances after this period of sterility some spermatozoa manage to work their way past the obstacle and to get at, and to fertilise, the ovum where it grows in this abnormal position, constituting one of the varieties of [illegible] great danger to the [illegible] through gonorrhœal

---

[2] Duncan, op. cit.

This power of travelling on the part of the spermatozoa is of great importance. Some years ago I was consulted by a young woman who was unmarried but who was four months pregnant. The hymen was not only intact but I could not pass my finger through the orifice it was so small. Obviously there had been no penetration and she was, so far as the law considers it, a *virgo intacta*. But she admitted to me that four months previously a married man had taken liberties with her and had actually spent and deposited his seed on to her vulva. But there had been no coitus in the ordinary sense and this was borne out by the condition of the parts. Nevertheless the spermatozoa had worked their way into the vagina from the vulva and had finally reached the ovum and impregnated it. When the semen is deposited within reach of the ovum obviously out of the thousands upon thousands of spermatozoa the liveliest and strongest is pretty sure to win the race and to reach the ovum first, and apparently when the spermatozoon has buried its head into the ovum changes begin at once which prevent any other spermatozoa arriving later from being able to penetrate also.

Again, you must remember that coitus is by no means synonymous with conception. Coitus is an act whereby the semen is deposited within the female. In a normal condition it is deposited in the vagina, generally in the posterior fornix. Sometimes no doubt it is ejaculated directly into the cervical canal and possibly directly into the uterine cavity and hence the occasional failure of thorough vaginal syringing immediately after coitus in preventing impregnation.

How long it takes for the spermatozoa after being deposited in the vagina to reach the ovum we do not know, but that it sometimes takes many days is extremely probable. You can imagine that if coitus took place just after a monthly period was over it would take longer than if it took place just before an expected period; for in the former case the ovum has only just started from the ovary and hence the spermatozoa would have to travel along the uterus and into the Fallopian tube before meeting with it; whereas in the latter case the ovum has already reached the uterine cavity where, in the human nest, the spermatozoa reach it without having far to travel. Hence many believe that the best time for coitus to take place, in order that pregnancy may follow, is just before an expected period; others think that the best time is just after a period is over. The Jews, who are just as prolific as other people, have strict laws on the subject. A certain number of days must elapse after a period is over, I think it is seven, and then the woman must take a bath in running water of a certain depth, width, and length, after which she is considered to be clean and coitus can be renewed. In the East-end of London rich Jews provide these baths for the poor people. In the West-end there are numerous baths of this kind for rich Jewesses. I believe the best time for a successful coitus to take place is a day or two before the "menstrual aura"[3]—i.e., the sensations which a woman has before the actual flow begins—generally more or less pain in the region of the ovaries for from a few hours to a day or two before the flow.

Some women will tell you that they know which particular coitus caused the pregnancy, because they had a different sensation at the time. But if you inquire carefully you will find that they are wrong so often that this supposed peculiar sensation is of no practical value. As a rule it is merely the orgasm. It is a prevalent idea that the orgasm is necessary. I believe myself that it is helpful, in that it is possible that it causes a better, more complete, and more copious emission on the part of the male, that it may perhaps cause some of the seed to be driven or drawn into the uterine cavity, and that it may help in bursting the Graafian follicle and setting the ovum free, or if already free, may assist it in its passage along to the normal goal—that is, the uterine cavity. But for impregnation neither pleasure nor desire is essential. I have known mothers of large families who have assured me that they have never had the least desire for coitus and have never derived the least pleasure from it. Nay, more, sometimes they positively loathe it and submit to it simply as a duty, but a duty which to them is abhorrent. And yet they have fallen pregnant and have reared large families. In other cases there has been some cause for agonising pain during coitus—pain which has destroyed all possibility of pleasure—and yet pregnancy has followed. Again there are many cases of pregnancy following rape. This may take place where the woman is unconscious, either from a blow, or during anæsthesia, or when she has fainted, or advantage may be taken of her when she is undergoing what she imagines is legitimate treatment; in which case she is quite innocent and, so far as she is concerned, the conception is immaculate. The fact is that desire and pleasure are merely nature's means for obtaining the deposition of the semen within reach of the ovum. If this is accomplished it does not matter much whether the desire or the pleasure is present or not, or whether the woman dislikes it, or suffers pain, or is unconscious or ignorant of what is being done, and therefore innocent; pregnancy can and does follow at times under each one of these conditions.

Anything that effectually prevents the ovum from reaching the cavity of the uterus will produce sterility or at best will only permit of an extra-uterine gestation. Beginning at the starting place you sometimes find the surface of the ovary so abnormally thick that the ova are unable to burst through; you may also get inflammatory products thrown out round about the ovary, so that even if the ovum does escape from the Graafian follicle it gets caught in the meshes of the more or less organised lymph and there perishes; or the ovary itself gets separated from the abdominal end of the Fallopian tube so far that the ova are not caught by the fimbriæ; or the fimbriæ become inflamed and are swollen and thickened and shortened and utterly spoiled as unerring egg-catchers. You may find them bent and twisted so that it is impossible to discover the ostium abdominale. You get peri-oöphoritis which binds the fimbriæ to the ovary so that any ovum that maturates has no chance of getting into the tube at all unless it happens to burst within the tiny area embraced by these adherent fimbriæ, and even then it is often unable to get far owing to the accumulation of a fluid which is the beginning of a tubo-ovarian cyst and which causes blocking of the ostium abdominale of the tube or of the canal of the tube not far from that opening. Again you may find the tubes bent, or stenosed, or, what is more frequent, distended with fluid through being blocked at both ends. The fluid may be purulent, watery, or sanguineous—pyosalpinx, hydrosalpinx, or hæmatosalpinx. There may be disease in the tube such as salpingitis, simple, gonorrhœal, or tuberculous. The tubes may be congenitally long or short or even absent, or stenosed or kinked. Sometimes the ostium uterinum is blocked and there are cases where an ovum has become impregnated whilst lying in that part of the tube which runs through the uterine wall. If when the ovum reaches the cavity there is anything there which will kill it, such as a gonorrhœal endometritis, sterility will ensue or if the uterus be absent then the ovum cannot enter it.

Anything which will prevent the spermatozoa from reaching the ovum will likewise cause sterility. The more vigorous the spermatozoa the greater the obstacles they can overcome. Mention has already been made of pregnancy following the deposition of semen on the vulva only. In imperforate hymen, in congenital absence of the vagina, in occlusion of a portion of the vagina, and in some congenital defects of the cervix uteri the spermatozoa are effectually prevented from reaching the ovum.

A very common experience amongst women is that the semen comes out after withdrawal, either at once or soon after or perhaps not until the erect posture is assumed. In this last case it may be a mere mechanical flowing out and not due to spasmodic contraction. Sometimes you get what is known as vaginismus, which is a painful contraction of the vaginal walls due to many causes such as urethral caruncle, lupus minimus about the hymen, small ulcers, vaginitis, pelvic inflammations, and the like, but the worst form of all is of nervous origin. Such cases, however, give rise more frequently to absolute dyspareunia, whereas in the cases I allude to, where the patient says the semen comes out directly or soon after coitus is over, you will often find a sensitive vagina which contracts on slight stimulation, but also one which contracts powerfully with both the muscle of the vaginal wall proper and with the levatores ani and other neighbouring muscular fibres which can diminish the vaginal capacity by contraction. Or you may find a disproportion in the relative parts; the vagina may be too short or too narrow; in other words, its capacity may be too small or the penis may be too big. In either case the vagina is stretched to an unusual degree during coitus and hence there is considerable elastic recoil post coitum. You will find, however, many women who are not sterile who experience this expulsion. Obviously the vagina could not expel every drop. Its walls would be at least wet with the semen after it had all apparently been expelled and therefore there would still be myriads of spermatozoa on the mucous membrane. Nevertheless it is better to remedy this if you can so that all the seed shall be retained. The vagina may be inflamed and there may be pus in it which kills the spermatozoa. Chronic vaginitis is a prolific cause of sterility. It may be simple but is mostly of gonorrhœal origin. If you see a recent case of gonorrhœal vaginitis—I mean one recently acquired—you will practically always find urethritis as well; hence the scalding micturition. In chronic cases there is a yellow discharge which is fatal to spermatozoa whether the gonococcus is present or not. Unfortunately gonorrhœal vaginitis is apt to spread upwards into the uterus and along the tubes to the peritoneum and so to set up mischief which produces a sterility which is incurable, besides leading to conditions dangerous to life. Hence the importance of dealing radically with gonorrhœa in women from the very first, attacking it especially in the urethra and cervical canals where the gonococci often lie hidden and escape from the germicidal lotions injected into the vagina. Green discharges in the vagina are often of an aggravated or more chronic form than the yellow. They are deadly to spermatozoa. There may be a watery discharge as from a vesico-vaginal fistula, or from a growth in the cervix, or from a fibroid tumour, or from some condition of the vagina. A watery discharge washes the semen away but it may not be so inimical to the life of the spermatozoa as the yellow or green discharges. If there be a recto-vaginal fistula the woman's complaint is not so much of sterility as that the fæces come through the front passage.

---

[3] The term "menstrual aura" is one which I coined when I left the National Hospital for the Paralysed and Epileptic in 1884 as it seemed useful to connote the subjective sensations which a woman has before her menstrual flow.

I remember operating on a woman who had a very severe labour in India. The perineum was torn right through the sphincter ani and for an inch or more up the rectum, so that the lower part of the rectum and vagina were converted into a common cavity or cloaca. Incontinence of fæces rendered her very wretched and miserable, but for several reasons she was unable to come to England for about three years after this accident and during those three years she had two more children. If a woman has had one child she has not been absolutely sterile. But she may have a very bad confinement and she may be greatly injured, so that you find a badly torn perineum and scars along the vagina and a deeply cleft cervix, with cicatricial bands running in various directions or even a tiny cervix, the bulk of it having been torn or having sloughed away. Hence the woman remains sterile afterwards and you find the cause in this scarred condition which prevents the spermatozoa reaching the ovum.

Routine vaginal syringing is a prolific source of sterility. Many women syringe knowingly to prevent conception, but some women who want children often syringe the vagina without thinking that it is spoiling their chances. You can readily understand that the fluid used in syringing is often fatal to spermatozoa, apart from washing them away mechanically. For example, a woman uses the douche in the morning and coitus takes place at night. No matter what fluid she has used—astringents, antiseptics, even plain water—all are inimical to the life of the spermatozoa and, of course, some of the fluid remains in the vagina. Moreover, constant syringing washes away the natural secretions which are obviously the proper fluid for the spermatozoa to live in. You may find the vagina dry and hot and leathery and the secretions coagulated from astringent injections. Similarly the various measures used to prevent conception damage the vaginal walls, making them harsh to the touch and often resulting in such tenderness that dyspareunia is the result.

4. That the Meeting Place should be a Suitable One.

The best place for them to meet is probably inside the uterine cavity—in fact, in the human nest. Perhaps in the Fallopian tube, where some think they most often meet, is equally good, only the ovum must quickly pass into the uterus or it would become attached to the tubal mucous membrane. For the meeting place to be in the ovary, or in inflammatory adhesions near it, or in the peritoneal cavity would obviously be bad. Again, if the ovum gets low down in the uterus it may result in an early miscarriage or in a placenta prævia. If it escapes into the cervical canal or into the vagina it is hopeless. There is no known case of an ovum taking anchorage and developing even to a slight extent within the cervical canal or vagina. The mucous membrane of these tubes seems to be incapable of giving attachment to an ovum.

5. That the Ovum after Impregnation should anchor inside the Uterine Cavity.

Possibly an ovum might be reached by the spermatozoa *whilst still in the Graafian follicle*; or it may be whilst still passing along the tube. But in any case it must, within a very short time of penetration by the spermatozoa, make its way into the uterine cavity and fix itself on to the mucous membrane in order that it may develop normally into a child.

6. *That the Human Nest (Endometrium) should be Healthy.*

Endometritis is another prolific source of sterility, more especially of relative sterility. A woman has one or more miscarriages, accidental, pathological, or artificial, during the first year or two of married life and then becomes sterile because the mucous lining of the uterus is chronically inflamed or otherwise spoilt as a nest. Curetting with a sharp curette may so destroy the endometrium as to render it incapable of carrying out its function. Similarly the application of too strong a caustic may irremediably damage it. The uterus may be tiny, undeveloped, immature, atrophied, or hyperinvoluted.

7. That there should be Nothing to prevent the Uterus from developing to Term or at all events to such a Time that the Child is Viable.

The presence of a fibroid in the wall of the uterus is a common cause of sterility. Often enough there is an accompanying endometritis. Moreover, the canal becomes tortuous and there is frequently a watery discharge which is apt to wash away the ovum. If conception takes place the uterus is unable to grow properly and miscarriage is the rule. The uterus may be obstructed in its growth by other tumours, or it may be bound down by adhesions, or it may be displaced. Curiously enough anteflexion is more commonly associated with sterility than retroflexion, though perhaps it is not in the nature of a cause but rather that it is found associated with sterility. Such women nearly always have scanty and painful menstruation and on examination you find a crescentic-shaped uterus with a conical cervix and an angle between it and the fundus more acute than usual. Probably the endometrium is largely to blame for the sterility. Retroflexion is more a cause of miscarriage than of sterility proper. Of course an inverted uterus could not sustain a child and in severe degrees of prolapse, partial and complete procidentia, there is often sterility for obvious reasons.

Sterility is divided into absolute and relative.[4] By absolute is meant where a woman never conceives at all—for example, in cases of congenital absence of the ovaries, or tubes, or uterus, or vagina. By relative is meant where a woman becomes pregnant but who either miscarries or if she goes to viability yet she only has one or two children and then she ceases to conceive.

Sometimes a woman consults you who has been married for some years and has never been pregnant at all. At other times a patient has had a miscarriage or more than one, or even a child living or dead, but she wishes for more children and yet none come. Now, in any given case that comes before you it will be necessary for you to find out the cause, if possible, in order that you may be able to remedy it. Assuming in the first place that it is the fault of the wife, you must find out her age and how long she has been married. If she is between 20 and 30 years and has only been married two years her chances are still very good supposing you discover no bar to conception. For it has been proved[5] that the number of first pregnancies during the second and third years of married life is very considerable, whereas there is a very big drop during the fourth year. That is to say, if a woman has been married more than three years without ever becoming pregnant her chances are much less than if she is only in her third year of married life. As already mentioned, a woman's best time for conceiving and bearing an average number of children is from 25 to 37 years.

---

[4] Matthews Duncan, op. cit.

[5] Matthews Duncan, op. cit.

The relative ages of husband and wife must be inquired into. An old man may in law be looked upon as capable of procreating, but after 50 years his powers are apt to wane and after 60 years his chances of getting children are poor. Where there is a great discrepancy in age it is as a rule the husband who is much older than the wife. A man, say 50 years of age or more, marries a girl 20 years of age. Such a marriage may be fruitful but it is not so likely as when the husband is only one or two years older than the wife and both are between 20 and 30 years of age. When the wife is very much older than the husband the chances of fruitfulness are very much less than under the converse conditions.

Sometimes you are told that during the first years of married life precautions have been taken to prevent conception, or if conception took place it has been got rid of by drugs or instruments. Perhaps this aversion to child-bearing was due to the idea that they could not afford. Sometimes it is pure selfishness, as the lady does not wish her pleasures, balls, parties, and the like, to be interfered with by pregnancy, parturition, and lactation. Later, when they are better off or when she sees some friend happy with her children, she feels she would like to have some herself. And so the precautions they have been using are omitted but to their chagrin and dismay no pregnancy follows. The precautions they have been using have damaged her. The vagina may be harsh and congested or inflamed. The os uteri may be eroded and the cervical mucous membrane inflamed and pouring out a copious white discharge. The uterine mucous membrane may be shaggy and pulpy, due to its fruit being untimely torn away. These are some of the ways in which sterility is caused by using precautions.

Again you may find that the patient has a yellow discharge and you may strongly suspect gonorrhœa. The woman may not have the least suspicion that she has that disease. I have seen cases where there was no doubt at all about it and yet where the husband denied ever having had it. As a rule, he will admit it to his medical attendant, especially if you tell him the importance of your knowing the truth. Notice any signs of masculinity: moustache or beard, hairs about the areolæ or over the sternum or along the front of the abdomen. Such women are often sterile. You will notice if the person is well developed—whether she has good breasts and nipples, whether her pelvis is well proportioned. It is best to measure the distances between the anterior superior spines and between the crests of the ilia. These should be about ten and 11 inches respectively. If they are less than this you may find an infantile pelvis and this may be due to want of development and, in fact, she may not have attained puberty, which would be found by eliciting other facts. The vulva, the development of the labia and mons veneris, and pubic hair should be noted and the condition of the hymen, imperforate, intact, lacerated, narrow opening, &c., or hermaphroditism. The presence of any cause of dyspareunia, such as urethral caruncle, kraurosis, lupus minimus, sores, venereal and other kinds, enlargement of glands in the groins, vulvitis, congenital defects in the vulva, hymen, vagina, uterus, or ovaries; vaginitis, urethritis, ruptured perineum from a past parturition, stenosis of the vagina or cervix uteri, congenital or acquired; cicatrices, pelvic cellulitis, pelvic peritonitis, hæmatocele, retro uterine effusions, uterine displacements, conical cervix, the length and width and general capacity of the vagina, and the condition of its mucous membrane as to rugæ, moisture, sensitiveness (vaginismus), and secretions. With a speculum note any tears or ulcers on the vagina or on the cervix uteri, also erosions and what kind of discharge there is, whether white, yellow, green, or red; or if there is any watery discharge or any growth in the vagina, the cervix, or the uterus, or any tumour in the pelvis or the abdomen. Note any fistulous communications with the bladder, rectum, cysts, abscess cavities, &c. Use a uterine sound and find out the length and direction and mobility of the uterus, also any stenosis of its canal, and the sensitiveness and vascularity of the mucous membrane. Make a bimanual examination and try to feel if the uterus is in its normal position and if you can feel anything in Douglas's pouch or above any of the fornices of the vagina. In Douglas's pouch you very often find the fundus uteri (retroflexion) or a prolapsed ovary, causing dyspareunia, or a distended tube, or some lymph from perimetritis or organised clot (hæmatocele).

Cases have been known where a woman has conceived after the climacteric; ovulation has apparently gone on for a short time after the change of life I have never come across such a case. My friend, Mr. W. Cock of Peckham, tells me he has had a case. At all events it must never be forgotten that ovulation may take place without menstruation and that therefore a woman may possibly conceive although she does not menstruate. If a woman did not ovulate she could not conceive. But in such a case she would not menstruate, for menstruation is absolutely dependent upon ovulation.

The normal healthy menses should be fluid, not clotted; they should be dark in colour and with an odour peculiar to themselves. Frequently in cases of sterility you find they are clotted or offensive, or like coffee-grounds, or that they contain fleshy pieces (membranes). These point to some morbid condition of the endometrium and may lead you to the cause and cure of the sterility. You should go fully into the menstrual history. Absolute amenorrhœa is generally associated with some congenital defect in the ovaries. Concealed menstruation is of course not amenorrhœa at all and as a rule is easily cured. Sometimes a girl ovulates but has never menstruated. In such a case you find she is well developed and very often she has monthly molimina. You may find a congenital absence of, or a rudimentary condition of, the uterus. The ovaries are present and acting well. In other cases she has a temporary amenorrhœa and she may conceive before menstruation is resumed. Hence women sometimes conceive during the amenorrhœa of lactation.

It will often be necessary for you to inquire regarding coitus. Very likely you may find there is pain which varies from a mere uncomfortableness to such agony as to prevent any penetration whatsoever. Or you may discover that excessive coitus is carried on. The sterility in such a case is probably due to a weakening of the male element. You will be sometimes astonished to find absolute ignorance in regard to coitus on the part of both husband and wife. I have met with cases where marriage has never been consummated through ignorance. In two such cases that I know of when it was explained proper coitus took place and pregnancy followed. In several cases, however, where after several years of supposed married life I found the lady a *virgo intacta* it has proved to be owing to impotency on the part of the husband from congenital or acquired causes.

TREATMENT.

What has been already said in discussing the diagnosis will have suggested to a large extent the line of treatment to be adopted, but I will summarise it and put it before you as one carries it out in actual practice.

1. *No treatment* —Where a woman is healthy and so far as can be ascertained there is no discoverable cause for the sterility and she has not been married for a full three years she may be left alone and told that she can still hope for progeny, but that if she does not become pregnant after, say, four years of married life she can then be seen again. I may mention here that when one finds that a woman has been married for some years but that marriage has never been consummated then the three years of married life must date from the consummation.

2. *Food and exercise.*—Obviously a spare diet and plenty of work, or its equivalent in physical exercise, will assist in curing the sterility. By a spare diet I mean plain food and not too much and not too often, with no alcohol of any description unless the patient requires it for some other reason. For example, a glass of bitter beer with her dinner is sometimes as good a tonic as can be given but as a rule I recommend no alcoholic drinks of any kind. Similarly the patient must give up taking any drugs, such as opiates or other sedatives. Where the patient is fat from ovarian inactivity and especially when the periods are scanty or absent I generally prescribe permanganate of potash in compressed tablets, one or two grains immediately after food three times a day. Of course, the adiposity here is physiological in a sense and if the ovaries can be got to resume active function the patient will soon get thinner. Especially if she begins to have babies will she get thinner.

It is a curious thing that not only do the poor and hard-working have more children than the rich and leisured classes but also they have a much larger proportion of male infants. In the Hunterian Oration which I gave in 1898 I showed that amongst the poor classes round about Guy's Hospital the proportion was 100 males to 89 females whilst amongst the descendants of the Queen the proportion was 100 females to 80 males. It is a well-known fact that excess of female births indicates weakness of productive energy. Professor Schenk of Vienna obtained some notoriety a few years ago by suggesting the possibility of controlling the sex by means of a particular diet. What we know of animal life, especially amongst bees, all seems to point to this, that in order to have male children the reproductive activity should be good and that therefore the diet should be spare. But however much a woman might starve herself she could not always succeed in having a male infant. Frequently I find a complete change of food is successful and by that I mean change of cooking as well. For instance, you send your patient back to her old home, or on a visit to a relative or friend, or to some holiday resort in England or abroad where she obtains quite a different kind of diet, cooked differently and served differently, and she becomes fertile although perhaps you have been trying other means in vain.

3. *Tonics.*—If a woman is in bad general health you would try to improve that as far as possible by giving suitable tonics. Poor women who are thin and prolific are strong as a rule. But a woman might be thin and weak from some cause of ill-health. It is curious, however, that in some cases of even profound ill-health a woman will breed easily. For example, in pulmonary phthisis you often find great reproductive activity right up to the end of the patient's life. I have myself delivered more than one woman in the last stages of phthisis and you will find as a rule in such cases that the child is plump and fat.

4 *Change of environment or climate.*—One of the best methods of treating sterility where there is no apparent bar to conception is a change of environment. Possibly the good results are obtained by a complete alteration in diet as has been already referred to. But that is not all. There is a great deal in the climate. Speaking broadly one may say that as a rule it is best to send the patient to a warmer climate. The influence of heat and cold upon fertility is very considerable. The beneficial effects upon ovarian activity of a hot climate such as India and South Africa and similar places are well known. Malta, Madeira, the south of France, and Italy all act in a similar though to a less degree and where patients are unable to go abroad I generally recommend the coast of Cornwall or Devonshire. Falmouth and Torquay are distinctly warmer than most parts of England. I have known cases where pregnancy has resulted from a change of residence to a colder climate, but perhaps the result was not due to that altogether, though no doubt some natures would be more fruitful in a temperate than in a hot climate. At all events we know that plants put in hot-houses will frequently bloom and fructify, whilst exposed to the ordinary atmosphere they are barely alive and quite or nearly barren. Also menstruation is nearly always improved, sometimes too much so, by living in a hotter climate. Many ladies return yearly from India suffering from menorrhagia. Moreover, hot climates develop to a large extent the sexual instincts, and although, as I have pointed out, these are not essential to fertility still they are helpful. It is often useful to send patients to hydropathic establishments or to some of the spas here or abroad. Personally, I frequently recommend country life—some quiet village as far as possible from a town—that is, when the patient already lives in a town. Also, after other methods have failed I sometimes get a patient to remove from one part to another in the place where she lives; for example, from the north to the south of London. Especially if I find, as is sometimes the case, that a patient is habitually constipated when living in a certain part and not so when visiting friends in other places. Probably in most of these cases it is the water-supply that causes the constipation. But whatever it is you eliminate it by a change of residence.

5. *Specifics*—Where the husband has had syphilis and the wife has had one or more miscarriages, thought to be due to inherited paternal syphilis in the developing ova, we should put the woman on a course of mercury or iodide of potassium. I think the former is the best, at first at all events, and I generally give it before she becomes pregnant again, and of course should she conceive then give it all through the gestation. In this way you will frequently succeed. Where there is no history of syphilis in the husband, but where there is no other discoverable cause of repeated miscarriages, I also recommend specific treatment.

6 *Local treatment.*—This would depend, of course, upon what was found on examination. You would cure any excoriations, caruncles, pruritus, or eczema. Repair any bad rupture of the perineum. Remove hypertrophied nymphæ if they are so long as to be in the way. Remove any tumours of the vulva. The hymen may be too thick or extremely sensitive and it may be necessary to incise it, or to cut pieces away, or to burn the sensitive patches. Cure any vaginitis that is present and be careful to pay special attention to the urethral and cervical canals, because it is from neglect of these that so many cases are only partially cured, the patient finding when she omits using the lotion you have prescribed that she gradually gets the yellow discharge back again. I generally prescribe lotio nigra for the vaginal douching and myself apply to the urethral and cervical canals a solution of nitrate of silver, ten grains to the ounce, by means of a Playfair's probe. This should be done at least every other day until the patient is cured. If after apparent cure the discharge returns it will be necessary to repeat the treatment and to do it more thoroughly. Any bands or rings or cicatrices on the vagina must be cut through in a suitable way. In vaginismus Sims's dilators or bougies may be used, also cocaine pessaries. Where the vagina is too short or too small in its capacity and whenever there is relative disproportion you should advise incomplete penetration. Where [illegible]—for example, too acrid— [illegible] ost coitum you can let the patient wear a polished vulcanite pessary and advise incomplete penetration so as to avoid the elastic recoil. In these cases I never recommend rubber instruments. An ordinary Hodge's pessary may do but I prefer a small Galabin's anteversion pessary which prevents the walls of the vagina from coming together and at the same time does not interfere with married life. Discharges of various kinds—red, yellow, green, white, or watery—must be treated according to their respective causes. In deep lacerations of the cervix trachelorrhaphy is beneficial as it prevents miscarriages when the cervical canal is properly closed. When the cervix uteri is too long or is thickened by hypertrophy of split portions you can remove pieces of it. Also the cervix uteri may be dilated or split, especially in those cases where there is a conical cervix or a small os uteri I generally perform a modification of Sims's operation by cutting through the circular fibres twice. This prevents reunion and subsequent closure by the retraction of the cut fibres Of course, one does this operation chiefly for dysmenorrhœa, but it is sometimes successful in curing the sterility, although not nearly so often as in relieving the dysmenorrhœa.

In cases of chronic endocervicitis you may have to scrape the mucous membrane with a sharp spoon or to apply a strong caustic. You would remove any polypi or other tumours from the cervix and treat any erosions that might be present. In some instances I have found that the mere passing of a sound for the purpose of discovering the length, &c, of the uterus has been followed by successful impregnation as if the sound had removed some obstacle or other. You can pass the sound or you may dilate with Hegar's dilators or some other form of dilator. I prefer Hegar's because they have a definite meaning. Each number refers to the diameter in millimetres. You can often dilate up to a No. 9 without an anæsthetic but it is better in many cases to give an anæsthetic and to dilate up to a No. 12 or 14—certainly if your object is to relieve dysmenorrhœa as well as to try to cure the sterility. When there is endometritis you may curette with advantage. Avoid a sharp curette or you may damage the nest. Apply tincture of iodine or liniment of iodine, or phenol, or iodised phenol, by means of a Playfair's probe, according to the strength of caustic required and this depends as a rule on the chronicity of the case; the longer it has existed the stronger the caustic required. Curetting is also useful when the menses are foul or clotted or profuse, or a bad colour, or like coffee grounds. Some advise the wearing of an intra uterine stem pessary, but this has practically fallen into disuse. The use of electricity is at present rather empirical. You might pass a current through with the negative pole in the uterus at one time and if this failed with the positive pole in the uterus at another; but I have known ladies spend much money on quack specialists who buoyed them up with hopes resting on an imaginary mysterious influence which the application of electricity would bring to bear. Remove any polypi or other tumours when possible. Remedy any displacements by suitable appliances or by operation.

With regard to the Fallopian tubes they are difficult to treat as they are quite out of one's reach except by operation. Where a double salpingitis has supervened on a gonorrhœa one can only attend to the general health and cure the gonorrhœa so far as it is accessible in the vulva, urethra, vagina, and uterus, and so hope that perhaps the tubes will in the end become so far better as to contain only a sterile fluid which will permit an ovum to pass along intact. Beyond this it is a question whether it would be possible to treat the tubes by abdominal section—that is, opening the abdomen and, as far as possible, separating any adhesions about the fimbriæ and perhaps passing a small probe along the canals of the tubes and applying some caustic. Considering the risk to life of this procedure and the impossibility of promising success in regard to the cure of the sterility I should never recommend it myself. But I have done this—namely, when it has been necessary to perform an abdominal section for some condition such as an ovarian tumour, finding the tube of the opposite side matted down or kinked I have separated the adhesions and placed the fimbriæ in as normal a position as possible, at the same time unravelling the tube and freeing it from any kinking.

Where ovaritis is diagnosed this must be treated by counter irritation such as blisters and tincture of iodine and giving hot water vaginal douches and whilst these are being given let the patient have physiological rest. Bromides may be given. Amenorrhœa due to various causes must be treated. When due to ovarian sluggishness you can treat it in the way already mentioned. Very often amenorrhœa is due to what the late Sir Andrew Clark called "fæcal anæmia" and it is best cured, as is also chlorosis with scanty or absent periods, by means of some easily assimilated preparation of iron such as pilula ferri, ferri carbonas saccharata (in powder), mistura ferri composita, and some saline purge such as the white magnesia mixture. As the producers of the ova the ovaries are the most important sexual organs in a woman and hence everything that can be done to improve their function should be tried. I can only hint at this by again referring to food, climate, permanganate of potash, &c. Where an ovary or both ovaries are bound down by inflammatory adhesions one must try to get absorption of the lymph by means of hot douches and absorbents such as mercury. I have no experience of massage in such cases and I think it would probably do more harm than good. The question of abdominal section with the idea of separating and freeing the bound-down ovaries I should be inclined to discuss in the same way as in regard to the tubes—namely, that if the abdomen had to be opened for some other reason one might at the time of the operation look at the ovaries and, if practicable, free them from the adhesions. Pelvic inflammations and hæmatocele must be treated by rest, real and physiological, hot vaginal douches, hot external applications such as poultices and hot flannels, and absorbents such as unguentum hydrargyri perchloridi and potassii iodidum internally and a little unguentum hydrargyri oleatis rubbed into the skin above the groins externally.

7. *Regulation of coitus.*—If possible remove any source of pain. Advise as to any excess. Suggest a day or two before the aura as the best time. In some cases advise complete abstinence for a period of time varying in different cases according to circumstances from a week to a month or more. Certainly it ought not to take place at all when you are treating the wife for gonorrhœa or anything which requires vaginal syringing, inflammations and the like. But the idea of abstinence is rather that of increasing the power of reproductivity. The male element may be improved by it. And possibly if the husband waited until there was desire on the part of his wife the chances of success might be greater. Find out if coitus is performed properly and advise accordingly.

8. *Natural habits.*—Find out if the patient is using a vaginal douche for any reason whatever. If there is a good reason—as, for example, in vaginitis—cure the condition if possible and then let her leave off all syringing so that the parts may get into a natural healthy condition.

Should all measures fail then you must turn your attention to the husband as the possible cause of the sterility. But I have not time to deal with sterility from that source. Artificial insemination is a wide subject with which I cannot deal here. But if you succeed in removing the barriers to conception and your patient becomes pregnant and goes to term and is delivered of a living child you will be amply rewarded by seeing the happiness in the mother's eyes as she fondles that little bit of humanity that is her very own.

A Clinical Lecture

ON

SEVEN CASES OF CÆSAREAN SECTION.

Delivered in the Leeds General Infirmary on Nov. 27th, 1903,

By J. B. HELLIER, M.D. Lond., M.R.C.S. Eng.,
OBSTETRIC PHYSICIAN TO THE INFIRMARY AND LECTURER ON
THE DISEASES OF WOMEN AND CHILDREN IN THE
YORKSHIRE COLLEGE, LEEDS.

Gentlemen,—In July last a married woman with a contracted pelvis came to this hospital to ask for attendance in confinement in the out-patient maternity charity. She said that she had had three previous labours. The first was certainly a craniotomy; in the second the neck was dislocated in attempts to deliver; and the third also had proved fatal to the child and she was very anxious to have a living infant. Her age was 28 years; her stature was 55½ inches. She had a small flat pelvis with a true conjugate of about two and a half inches or a little less—say six centimetres. She was in good health and labour was expected about the second week in September. It was explained to her that if she would come into the hospital on Sept. 1st and undergo the operation of Cæsarean section in all probability her child would live and she would recover. Having understood the nature of the operation and having consulted her husband she consented and was admitted on Sept. 2nd. She was prepared for abdominal section in the usual way and no one was allowed to make a vaginal examination. Without waiting for labour to begin the operation was put down for performance in the general theatre on my usual Saturday morning list. She was anæsthetised with ether by Mr. D. Seaton. Our aseptic technique now includes the wearing of sterilised rubber gloves by all persons concerned, including dressers and nurses. To incise the abdomen and uterus and to deliver a living child occupied two and a quarter minutes. The uterus was then drawn forwards through the abdominal wound and all bleeding was controlled by an elastic cord while the placenta and membranes were removed and the uterus was very carefully stitched up. The uterus contracted and retracted well and after the elastic cord had been removed and the uterus returned there was no further hæmorrhage. The patient bore the operation exceedingly well and on the next day looked better than the average primipara on the morning after labour. The temperature reached 100° F. on the second night and then became normal. There were no complications and the wound healed by first intention. The child was put to the breast at intervals on and after the second day, a plentiful secretion of milk began on *the third* day, and on the twenty-second day the mother and child were discharged in excellent health. The child weighed 6 pounds 14 ounces at birth and 8 pounds 2 ounces on discharge. Thus the hopes which had been held out to the patient last July were fully justified.

Cases in which Cæsarean section is contemplated may be divided into those where operative conditions are perfectly satisfactory and under control and those where they are more or less unsatisfactory. The case just mentioned is an example of the former. It is a good example of modern Cæsarean section, an operation neither difficult nor very dangerous. We can not only perform it with confidence in those cases of extreme pelvic contraction where the indications for it are "absolute" but we can offer it to our patients as a fairly safe alternative to the termination of pregnancy by the destruction of the unborn child. To the mother such a proceeding is most miserable and depressing, especially when repeated again and again. To the obstetric surgeon it is essentially repugnant in its nature and ghastly in its details. It is, moreover, in all high degrees of pelvic contraction attended with very appreciable risk.

To you, gentlemen, the operation may seem to be so simple and straightforward that you may fail to realise how now a thing it is in the history of obstetrics that any degree of safety should be ascribed to the operation of Cæsarean section. When I was a *student* Dr. Robert Barnes described it as "occupying a doubtful place between conservative and sacrificial midwifery" and as being "resorted to with a feeling akin to despair for the fate of the mother which was scarcely tempered by the hope of saving the child" It will not be a waste of time if we take a brief glance at the past history of our subject.

Cæsarean section is the oldest of all abdominal sections, the oldest by many centuries. Most modern abdominal sections are the result of the safety of aseptic surgery, but Cæsarean section and later ovariotomy were formerly undertaken in ignorance of the most essential conditions of success. In fact, the development of modern abdominal surgery springs largely from experience gained in the performance of ovariotomy and the application thereto of aseptic principles. In early times Cæsarean section was performed simply to save the child. It may be that the house of the Cæsars derived its name from one born, as Pliny tells us, by *incision* of his mother's womb—*a cæso matris utero*[1]—just as Macduff is said to have been

> "From his mother's womb
> Untimely ripped."[2]

But this was not surgery and our interest begins with the day when the mother's life was put first. The first time the mother's life was saved is said to have been in the year 1500 A.D. and the account of this operation may be new to most of you. I take it from Herrgott's French translation of Siebold's "History of Obstetrics."[3] If it is true it is the story of a very brave deed. In the year 1500 Elizabeth Alespach, wife of Jacques Nufer, a pig-dealer in the village of Siegerhausen in Thurgovie (near the Lake of Constance in Switzerland), being pregnant with her first child and having felt labour pains for several days summoned 13 midwives in succession to her assistance as well as some *lithotomists*. They made many attempts to deliver her but all were futile. As her sufferings were acute and as she had abandoned all hope of relief her husband told her that if she could trust him he would undertake an operation which, by God's grace, might succeed. His wife answered that she would endure anything to get relief. As the matter was a delicate one the husband went to the Mayor of Frauenfelden, the capital of the canton, to ask permission to undertake the operation. The mayor made some difficulty at first but being satisfied as to the condition of the woman and the good faith of the husband he gave consent. The man returned home and told the midwives that those who had sufficient courage to assist him might remain in the room but those who were afraid had better go out as he was about to undertake something by which he hoped, with God's help, to save his wife. 11 of the midwives grasped and admired his purpose but retired. Two, more courageous, remained with the lithotomists to render help. After having prayed for Divine assistance and carefully fastened the door he laid his wife upon a table and made an abdominal incision as he would have done with a pig (the man being no doubt accustomed to spaying sows). At the first cut he opened the abdomen so successfully that the child was extracted uninjured. The midwives outside the door heard the child c[illegible] vain, for they were not admitt[illegible] ished and the wound had been [illegible] eterinary surgeons. The wound healed well and the woman recovered without any bad symptoms. As she subsequently bore six more children, two being twins, there cannot have been any serious degree of pelvic contraction. The child rescued by the operation died at the age of 77 years, leaving wife, children, and grandchildren. This story has the appearance of truth. Siebold thinks that some doubt is thrown on the question of this being a case of Cæsarean section by the fact that there is no mention of any incision in the womb in addition to the abdominal incision, and as she bore children naturally afterwards it is suggested that this was really an extra-uterine fœtus. There seems to me to be no weight in the first objection; a bold incision would be more likely than not to open the uterus simultaneously with the abdomen as anyone who has experience in the operation will realise. It is not difficult to imagine that a woman might be in bad pain for some days and that she and the midwives might be alarmed and in despair in the presence of some condition not incompatible with subsequent normal labours. Version was but little known in Europe till the time of Ambroise Paré, and midwives and "lithotomists" and barbers might easily be at the end of their limited resources. The question of the fate of the placenta in abdominal pregnancy is a very serious matter and the facts that the wound healed by first intention and that the woman recovered without a bad symptom and that the child was the reverse of puny and short-lived are considerations which incline me to accept the case as one of Cæsarean section. So much for Nufer.

This was 400 years ago and during the greater part of these four centuries attempts to practise the operation have resulted in a most appalling mortality, so that even during the greater part of the nineteenth century accoucheurs were largely occupied in inventing osteotomists, cephalotribes, cranioclasts, basylists, basiotribes, and other instruments for destroying the child in order to supersede as far as possible the performance of hysterotomy. If you will take from the library shelves a treatise on obstetric medicine published in 1836 by Dr. Davis in two most beautifully illustrated quarto volumes, you will find a figure of an "osteotomist" which he invented and which he thought would "have the effect of reducing almost to zero the necessity of having recourse to that last extremity of our art and the forlorn hope of the unhappy patient, the Cæsarean operation." Ramsbotham in 1841 gives the statistics for the British Isles as 30 cases with 27 deaths. I notice that he says that sutures are not needed for the uterine wound but that two or perhaps three will be required for the abdominal incision.[4]

I have already quoted Dr. Barnes's despairing utterance in 1871 and this was a time when ovariotomy was a well-established operation. The British mortality from Cæsarean section was at this period 84 per cent.[5] In a very valuable French treatise on obstetrics Budin tells us that in 1876 there had been no successful case in Paris since 1787.[6] It was from 1876 that we may date the beginning of better things. The method of removing myomatous uteri by supravaginal hysterectomy with an extraperitoneal pedicle secured by a serre-nœud and fixed in the abdominal wound had been successfully practised by Péan of Paris and by Koeberlé of Strasburg. Professor Porro of Pavia realised that such a treatment of the puerperal uterus after Cæsarean section would save the patient from some of the chief dangers of the operation as hitherto performed, and he introduced the operation known as Porro's operation which is described in every text-book of midwifery. The better results of this operation became obvious at once and the mortality continued to fall as aseptic principles were developed and applied to it. Eight years later Dr. C. Godson[7] collected the statistics of Porro's operation up to date and found that the mortality was 56·57 per cent. That is, about half the cases were being saved. It seemed likely that Porro's method would oust the old operation completely, but in 1882 Saenger of Leipsic designed the modern operation known as conservative Cæsarean section or Saenger's operation. He succeeded in convincing the profession that the principle of sacrificing the womb is wrong and his operation is in principle, if not in all its original details, now regarded as the best method of delivery by abdominal hysterotomy. The mortality of Saenger's operation to-day in 355 cases by the most experienced operators is under 7 per cent., while in cases not infected [illegible] 4 per cent. Zweifel has had [illegible] se figures are quoted from one [illegible] works on obstetrics, Professo[illegible] text-book. Saenger died in January, 1903, at the early age of 50 years, and the loss of this gifted, original, and many-sided man is much to be lamented In 1898 Leopold of Dresden had completed 100 cases with a mortality of 9·8 per cent. for the conservative operation and 10·3 per cent. for Porro's operation.[8] He is said to have performed more Cæsarean operations than any other man. The longest series of such cases will always, we expect, come from abroad. Contracted pelvis occurs in many parts of the continent with a frequency which is unknown in England. The Germans call rickets *die Englische Krankheit*. They see plenty of it themselves. We certainly may describe osteomalacia as a continental disease. There it is endemic and frequent, here it is sporadic and rare.

In the modern conservative operation success depends upon three things—viz.: 1. The most rigid asepsis. No operation owes more to aseptic surgery than this. I do not know whether Lord Lister ever performed a Cæsarean section, nor do I know how long it may be since he attended a confinement; but every successful case of Cæsarean operation owes her recovery largely to him, and every woman now attended in labour by a civilised practitioner has a debt to Lister. 2. Efficient suture of the uterine incision so as to prevent any leakage of lochial fluid into the peritoneal cavity. 3. Early operation. This means the performance of operation not as a last resource when other means have failed and when the patient is exhausted by protracted labour and the parts are infected by prolonged digital and other manipulations, but at the earliest suitable time when the strength of the patient is at the maximum and the parts are untouched.

The ideal conditions for operation are most perfectly realised when the pelvic contraction which necessitates the operation has been diagnosed beforehand, so that no vaginal operation needs to be made at the time. A day and hour can then be fixed, all requisite preparations can be completed, and the hysterotomy can be performed without waiting for labour to begin. It is a most interesting physiological fact that if the pregnant womb be thus incised and evacuated retraction and spontaneous arrest of hæmorrhage will take place as in an ordinary labour. The principle is not really new. It has been known for a long time that rapid delivery by *accouchement forcé* does not necessarily involve post partum hæmorrhage. Recent experience with Bossi's dilator has shown that retraction will follow evacuation of the womb by this process also. For example, in a recent case of eclampsia before labour had set in I dilated the cervix with Bossi's dilator and delivered the child with forceps within 45 minutes. The placenta came away soon after and there was no post-partum hæmorrhage. Ideal conditions for the operation cannot always be secured. This is obvious. The pelvic contraction may not be discovered till labour has commenced. Our cases here are often admitted in labour and may have been brought from some distance, but the earlier the operation the better the result. Cases unsatisfactory for this operation are such as have been subjected to fruitless attempts to deliver per vias naturales by forceps or turning; cases where the membranes have been long ruptured and repeated vaginal examinations have been made, where the pulse has become rapid, the temperature raised, the uterus tonically contracted, and the patient exhausted. In such cases if the indications are "relative" the best plan usually is to deliver by embryotomy and to perform Cæsarean section if a subsequent pregnancy should occur. If the indications are "absolute" then hysterotomy followed by hysterectomy is the best plan.

The objections to Porro's operation are that it is in most cases a needless mutilation and a greater shock. The fixing of the pedicle in the wound is an unsurgical procedure. It necroses, becomes more or less septic, and when it separates a large cavity is left to granulate and a weak place is left in the abdominal wall where ventral hernia is very apt to develop. If it is thought that hysterectomy is indicated it is better to carry out the operation of supravaginal amputation of the uterus with retroperitoneal pedicle. This is said to be an easy operation under these conditions of large abdominal incision and lax pelvic tissues and not to occupy more time than an ordinary Porro's operation[9]

Since my appointment to this hospital four years ago I have performed conservative Cæsarean section seven times with six consecutive recoveries.[10] For the general details of the operation I refer you to your text-books. I propose here to say a few words about certain points which have struck me and certain questions which arise in connexion with the subject. I give first a list of my cases.

CASE 1—The patient had been married nine years and had had five dead children. She had a flat pelvis with a conjugata vera of two and three-quarter inches. Cæsarean section was performed on May 20th, 1900, labour having commenced. Hæmorrhage was controlled manually. Salpingectomy was performed. The child lived but the mother died on the seventh day from broncho-pneumonia and suppuration in the uterine incision (see note on this case).

CASE 2.—The patient was married and a primipara, her age being 24 years. Her height was 4 feet 6 inches. The conjugata vera was two and a half inches. She was admitted in labour. Cæsarean section was performed on Nov. 21st, 1900. Hæmorrhage was controlled manually. Salpingectomy was also performed. The child lived. The wound healed by first intention and the mother made a good recovery.

CASE 3.—The patient was a primipara, married, and aged 25 years. She was the subject of rickets. Her height was 4 feet 7 inches and she had a conjugata vera of two and three-quarter inches. She was admitted in labour on Sept. 6th, 1901. The funis was prolapsing. Cæsarean section and salpingectomy were performed. An elastic tourniquet was used. The mother recovered without complication. The child was stillborn, having been killed by pressure on the cord.

CASE 4.—The patient was single and aged 33 years. She was a rachitic dwarf, her height being 3 feet 1 inch. Her limbs and pelvis were much deformed. The conjugata vera was two inches. She was admitted in labour Cæsarean section was performed on August 27th, 1902 Some ascitic fluid was present in the peritoneal cavity. Hæmorrhage was controlled manually. Salpingectomy was also performed. The child lived and the mother recovered without complication.

CASE 5.—The patient was married, a primipara, and aged 28 years. Her height was 4 feet 3 inches. She had a badly-contracted rickety pelvis. The conjugata vera was one and three quarter inches. She was admitted in labour. Cæsarean section was performed on Jan. 1st, 1903, the presentation being transverse. The cord was prolapsing. A little ascites was present. Hæmorrhage was controlled by elastic tourniquet. Salpingectomy was afterwards performed. The child was stillborn. The mother recovered without any complication.

CASE 6.—The patient was a primipara, single, aged 27 years. She was a rickety subject. Her height was 3 feet 8¼ inches. The conjugata vera was two inches She was admitted in labour. Cæsarean section was performed on June 21st, 1903 A little ascites was present. Salpingectomy was also carried out. The mother and child recovered. The child's head was deeply dented at the parietal bone by the sacral promontory on the attempt of the head to enter the pelvis. The head was normal in a few hours after birth. Some suppuration in the uterine wound took place, which was treated by draining (see note below). The mother recovered perfectly.

CASE 7.—The patient was aged 28 years. She had had three previous stillborn children. The conjugata vera was two and a half inches. Cæsarean section was performed on Sept. 5th, 1903, before labour had commenced. Hæmorrhage was controlled by elastic tourniquet. The mother and child recovered without complication. The mother suckled the child.

Abdominal incision.—In all my cases the abdominal wall has proved to be exceedingly thin. It has consisted in the middle line of skin and fasciæ aponeurosis, and peritoneum, no fat and no muscle. The first stroke of the knife may easily open the abdominal cavity and nick the uterus; the abdominal incision should not come too low down. Its centre may lie at the navel; this enables you to make the uterine incision sufficiently high, also it avoids the bladder. All who do abdominal surgery must bear in mind the possibility of a high bladder. In cases of myoma uteri and in pregnancy and other conditions the *reflexion* of the peritoneum from the abdominal wall to the bladder may be seated as high as the mid-point between the navel and the pubes. Hence, if an incision extend too near the pubes the bladder might be opened instead of the peritoneum. I have seen this only just avoided by experienced surgeons. Open the peritoneum first at the upper end of an abdominal incision. The point is mentioned in some text-books but needs emphasising.

Ascitic fluid —In Cases 4, 5, and 6 a little free ascitic fluid was found in the peritoneal cavity. No special importance needs to be attached to this and perhaps it may be *not* uncommon in pregnancy.

The uterine incision.—This must not be too short otherwise it will tear during the extraction of the child and it will probably tear downwards where the wall is thinnest. The incision, which should be six inches long, should be well above the retraction ring Suturing is more efficiently carried out in the thicker wall of the fundus. Probably also a wound here is somewhat more secure from stitch abscess

---

[9] W. Williams loc cit.

[10] Details of Cases 2, 3 4 and 5 have been published in the Brit. Med. Jour., Jan. 6th and Nov. 2nd, 1901, and Jan. 3rd and March 14th, 1902.

than one in the thinner wall of the lower segment near the vagina. The incision is easily made. Cut an aperture with a scalpel to admit the index finger and then use a large pair of scissors with finger as director. Never mind the placenta If you come upon the centre cut boldly through it or if upon [illegible] seems to give [illegible] ion. As soon as the child is born your assistant presses the cut edges of the uterus together and draws the fundus forwards out of the abdomen. The abdominal cavity is then carefully packed off with large sterile swabs. By compressing the broad ligaments the hæmorrhage can be controlled manually or an elastic cord can be placed round the cervix. This sets your assistant's hands at liberty to help you. Some operators use the cord regularly; some avoid it for fear of causing uterine inertia. I do not think the risk of this is great. When the sutures are tied the bleeding from the uterine incision ceases. If you are using the tourniquet you take this off when the last silk stitch is tied. If there is bleeding at any point of the wound you may decide to pass another suture there. I have always followed the book, passing deep silk sutures through all the wall except the mucosa with intermediate stitches half-way through. Finally, a continuous catgut suture, passed Lembert-wise, is carried down the wound, closing the peritoneum over the other sutures and burying them out of sight.

How to secure uterine contraction.—Before returning the uterus into the abdomen you may squeeze it between your hands to empty it of blood and to make it contract If at this point you pour hot water at from 110° to 115° F. over the peritoneal surface of the womb it will contract promptly and firmly. Hot intra-uterine injection has long been used for post-partum hæmorrhage, but it is very pretty to see from the outside the effect of hot water on uterine contraction and retraction. I would advise anyone to try this who may have difficulty with uterine inertia at this stage.

The question of sterilisation.—Porro's operation made subsequent utero-gestation impossible. In the conservative operation sterility can be almost certainly secured by excising a considerable segment from each oviduct. This I have done in six of the seven cases here mentioned. It is quickly done and adds practically nothing to the risk of the operation. To-day some practitioners question the propriety of this step, saying that it is no part of the duty of the profession to [illegible] ures, even if the woman and [illegible] to me that if a woman be [illegible] for her to be delivered of a living child except by abdominal section, so deformed, that is to say, that parturition cannot take place physiologically; then the operator does right to take steps to protect the woman against further pregnancy and parturition if this is the wish of the parties concerned.

The closure of the abdominal wound and the after-treatment follow the lines of ordinary abdominal section.

Lactation after Cæsarean section.—In the last case the mother was allowed to suckle her own child with the best results. I shall adopt this plan in future when the mammæ are secreting well and the mother's condition is satisfactory It is best for her and best for the child.

Suppuration in the uterine wound.—We all know that from time to time one sees a stitch abscess or a limited area of suppuration in the wound after abdominal section. This is not usually a very serious matter. It sends the temperature up on the fourth or fifth day and when the pus is let out things become normal again. The perfecting of aseptic precautions has greatly diminished the frequency of such an occurrence, but I know no one in whose practice it *never* happens. Now a stitch abscess may occur in the uterine wound, where it is a more serious matter, for it may lead to suppurative peritonitis. You can guard against this by having (1) aseptic hands, (2) aseptic instruments, and (3) aseptic sutures. But there is a fourth requisite, an aseptic uterine cavity. This is the great reason why those cases do best when there has been least vaginal examination. Yet the fact that we have not touched the patient does not necessarily secure the absence of infection. For example, I may remind you that children are sometimes infected in the genital canal by maternal secretions and so develop ophthalmia neonatorum. Supposing that for any reason a uterine stitch abscess should occur it would cause a rise of temperature about the same time as a similar condition in the abdominal wound. It does not follow that the local signs would be very pronounced, especially at first. There might be little pain or distension and no great tenderness. But if you had any reason to be uneasy about your patient you ought to take out the lowest stitch in the abdominal wound and to insert a small drainage-tube into the utero-vesical pouch. You shall hear how this lesson was learned. The patient in Case 1 died on the seventh day. After operation she had broncho pneumonia which was ascribed to ether. On the second day onwards there was some rise of temperature. The abdominal signs were trivial or almost *nil*. The constitutional symptoms seemed to be fully accounted for by the obvious lung conditions. On the seventh day she grew worse and died somewhat suddenly. At the post-mortem examination there was purulent peritonitis which seemed to have started from the lowest uterine stitch or stitches. There was a considerable local collection of pus. I determined that if ever a case gave me similar anxiety I would explore and drain. In Case 6 this lesson was put to use. On the second day there was some rise of temperature for which I could not account. The abdominal signs were almost *nil*. No distension was present but just a little tenderness above the pubes. The lowest abdominal stitch was taken out and a small drainage tube was put in the utero-vesical pouch. No discharge escaped at the time. Next day there was a discharge of pus, the temperature fell, and though the sinus continued to discharge for some time the woman made a good recovery. Probably Case 1 might have been saved in the same way.

Absolute and relative indication.—The limit of absolute indication should not be less than 2·5 inches, or six centimetres. In 1871 Dr. Barnes put it at 1 5 inches. In Vienna to-day it is 6 5 centimetres; in Germany 5 5 to 6 centimetres The tendency is to extend it to seven centimetres.[11] As to symphysiotomy, it is being discarded in favour of Cæsarean section and you are not likely to see it performed here. In cases where the indications are "relative" Cæsarean section will certainly be performed more frequently in this country than in the past as an alternative to craniotomy as the safety of the operation when performed under favourable conditions becomes generally recognised. The country practitioner called to the primipara in some one-roomed cottage on the hill side far away from any other practitioner's help may be still obliged to destroy the child. But such a case in the event of a second pregnancy may be sent to a hospital for treatment when term approaches. And the number of hospitals, larger or smaller, where thoroughly aseptic surgery can be carried out is constantly increasing and there are comparatively few who are beyond reach of such. The days when embryotomy was expected to supersede Cæsarean section are over. To-day this expectation is reversed.

Here then, gentlemen, is an operation which at one time seemed almost hopelessly fatal and which a quarter of a century ago had a mortality in Great Britain of four cases in five. To day it is undertaken, not with despair, but with confidence. The mortality has been reduced to one twelfth of what it was then. Given early operation and favourable conditions the mother and child will probably be saved. This is a great triumph and we who record successes to day may well bear in mind how large a proportion of the credit belongs to those who have gone before us. We walk in a plain path which they have made easy for us by their patient investigation, their scientific enterprise, and, we may add, by their honest records of their failures.

KELLY'S METHOD OF CYSTOSCOPY IN THE FEMALE.[1]

By THOMAS WILSON, M.D. LOND., F.R.C.S. ENG.,
OBSTETRIC OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM; HONORARY SURGEON TO THE LYING-IN CHARITY, ETC.

AMONG the women who apply for treatment for affections of the organs peculiar to their sex are many who complain of symptoms arising from the urinary tract. In many of these cases the symptoms are due to some condition that primarily or chiefly affects the urinary organs, while in a very much larger number they arise from a disturbance of function set up by some affection of the neighbouring uterus or its appendages. The recognition of some disease of the latter organs and the prompt subsidence of urinary symptoms when this disease is treated often appear to prove the dependence of one upon the other. Not uncommonly, however, it happens that some organic affection of the bladder, urethra, or other part of the urinary tract co-exists with some affection of the generative organs, such as a retroversion of the uterus or an inflammation of the ovary or Fallopian tube. In such cases the measures which relieve the symptoms due to one affection may entirely fail to relieve those due to the other. Take, for example, a nulliparous married woman, aged 32 years, who was first seen in an acute attack of pelvic peritonitis; a month later there was left salpingo-ovaritis with retro-position and anteflexion of the uterus. Nine months later, on Oct 13th, 1898, urinary symptoms, especially frequency of micturition, persisted, although the condition of the ovary and tube appeared to have recovered. Cystoscopic examination disclosed on the posterior part of the floor and on the posterior wall of the bladder small areas of dark redness, from the size of a pin's head to that of half a split pea, with areolæ of a brighter red gradually shading off into the normal mucous membrane [2]

[1] A paper read before the Midland Medical Society on Dec. 2nd, 1903.

The methods by which we endeavour to decide whether the functions of the bladder are disturbed by some disease that may be present in the neighbouring organs or tissues, or whether these symptoms really depend on some affection of the urinary tract itself, include in the first place examination of the urine, to ascertain whether this secretion is normal or presents any of the well-known changes set up by disease, such, for instance, as alkaline reaction or the presence of mucus, pus, or blood. Palpation of the lower abdomen, inspection of the meatus of the urethra, palpation of the urethra, and bimanual examination of the bladder may in some cases throw light on the causation of any urinary symptoms that may be present. The use of the sound enables us to detect certain gross conditions within the urethra or bladder, such as the presence of a stone or foreign body or occasionally of a firm tumour.

In doubtful cases where the symptoms are severe Simon's method of dilatation of the urethra and examination of it and of the interior of the bladder by the finger may enable us to determine alterations in the walls or contents of the bladder. It may still, however, happen that small ulcers or even soft papillary outgrowths may be present in the bladder and that they may be unrecognisable by any of the methods of treatment hitherto mentioned and in such cases it is only possible to make the diagnosis by means which will enable us to make a visual inspection of the interior of the bladder. There are two methods of making this inspection. The first depends upon the injection of water into the bladder and the employment of Nitze's electric cystoscope or some of its modifications. The second more direct method depends upon the passive distension of the bladder with air and was placed upon a firm basis by Howard Kelly who gave a full description of his method in the *American Journal of Obstetrics* for January, 1894 Since October, 1898, I have used the latter method on nearly 250 occasions and have satisfied myself that it is a scientific method of great practical value. It depends for its success upon the important fact that when the pelvis is raised above the level of the rest of the trunk the intestines gravitate towards the diaphragm and then if the urethra is opened air rushes into the bladder and distends it. The influence of Sims's position, and still more of the knee-elbow position, in causing negative pressure in the vagina was long recognised and an occasional ballooning of the bladder had also been observed and is mentioned, for instance, by Winckel.[3] Pawlik appears also to have been conversant with this phenomenon, but it remained for Kelly to make a systematic use of the fact and to apply it as a means of enabling a direct and thorough inspection of the interior of the bladder to be made The necessary instruments for Kelly's method are now well known. The specula employed are essentially cylindrical thin metal varying sizes, numbered according to the metres. They are provided with a handle an for convenience of manipulation and with an obturator facilitate introduction. The necessary light is obtained by means of a small lamp fixed on a forehead band reflected from an oil, electric, or other lamp by a mirror.

The method of carrying out the examination is as follows. The patient lies on the back with the knees drawn up and separated. The bladder is emptied catheter, then the urethra is measured by a calibrator, and the appropriate speculum, usually to ten millimetres in diameter, is chosen and passed. patient is now allowed to rest for a minute or and is assured that what remains to be done will not her. The sacrum is then raised from eight to 12 above the table by means of bran or sand pillows, the are flexed on the abdomen, and each is supported by a or assistant, one of whom holds the lamp or other source light to be employed. The observer adjusts his mirror so as to project the light into the speculum and by appropriate movements can then inspect the whole of the bladder. When this has been done, as the is withdrawn, the mucous membrane of the urethra examined. As the end of the speculum is withdrawn into the upper end of the urethra the patient complains of pain and during the examination of the bladder complaint of pain generally means that the speculum been withdrawn so far that its end has engaged in urethra; care should accordingly be taken to avoid The upper part of the urethra closes over the end of speculum as this is withdrawn in a flat funnel shape. the upper end the colour of the mucous membrane with radial brighter red bands converging to the closed lumen of the urethra, these bands representing folds in the mucous membrane. In the lower third, rather more, of the urethra the colour of the membrane becomes duller and more opaque red. the withdrawal of the speculum the sacrum is by removing the pillows and a catheter is passed to let out the air from the bladder. If this is not the woman is apt to experience severe collicky pains in the lower abdomen owing to the presence of the air in bladder. After the examination a short rest and a small dose of aromatic spirit of ammonia are desirable in some cases and the patient may be warned that for the time or two after the examination micturition may be accompanied by some smarting. With this exception examination causes no inconvenience.

Now let us consider briefly one or two practical points the first place, as regards the necessity or otherwise for anæsthesia. Occasionally where the bladder or urethra excessively tender it may be desirable to administer general anæsthetic; in other cases the use of a 10 per cent. solution of cocaine to the urethra is required, but in great majority of cases, at least 90 per cent in my own experience, neither local nor general anæsthesia has been required. In the next place, as regards the position of the patient it may be said at once that the knee-elbow is more efficacious than the raised sacral in giving rise to of the bladder and, indeed, Kelly appears to recommend the former as the routine position. It is, however, tionable not only on æsthetic grounds but because, also, very quickly tires the patient Moreover, I found that of 200 cases in my own experience, in 150 the raised position brought about satisfactory ballooning. In practice, therefore, the knee-elbow position has been reserved for those cases, much the least numerous, in which ballooning does not occur in the raised sacral position. when the bladder does not at first expand air enters freely as the examination proceeds, but the times happens Failure to balloon may be due to causes, of which the chief one is obesity; in fat ballooning does not take place in the raised sacral and is sometimes unsatisfactory even in the position. Occasionally, again, urine is left even after careful attempt has been made to empty the bladder by catheter or by the patient herself, or it may happen that a rapid secretion of pale nervous urine is taking place. If amount of urine thus present during the examination a few drachms it is apt to interfere with a proper view and requires to be withdrawn by means of the evacuator, simple elastic suction apparatus. It is hardly necessary to add that the greatest care must be taken in cleansing the vulva and in using only sterilised instruments and carefully prepared hands.

---

[2] This bladder appearance was suspected to be tuberculous Lately my friend Dr H. P. Motteram has been good enough to inform me that he has been attending this patient and that when he was called in first two or three months ago the bladder trouble had been getting worse, there were emaciation and night-sweats; the kidneys were not enlarged or unduly tender. There were tenderness at the neck of the bladder and apparently thickening of the bladder wall. The patient improved much after rest in bed and washing out the bladder with sulphate of copper solution.

[3] Billroth and Luecke's Handbuch der Frauenkrankheiten, Band iii., p. 344, 1886.

If now we compare Kelly's method of cystoscopy with electric cystoscopy we shall agree that both require practice, but I think we shall also agree that Kelly's method can be acquired with greater ease than the other. In neither method is an anæsthetic necessary in an ordinary case. The employment of Kelly's method demands more assistance than the electric method; the latter can be carried out on a suitable table even without any help, whereas the former requires at least two nurses or assistants. Further, it is not always possible to obtain a view of the inside of the bladder by Kelly's method; thus, for instance, in a patient, aged 67 years, with profuse hæmaturia I failed on three patient attempts without anæsthesia to obtain a satisfactory view of the inside of the bladder. Mr. Gilbert Barling examined the patient under an anæsthetic with the electric cystoscope and pronounced the bladder to be normal. The patient died later and the necropsy revealed right pyonephrosis and a left calculous kidney.

On the other hand, electric cystoscopy depends for success on the injection of water under pressure, which is not devoid of danger; moreover, when bleeding is going on the fluid becomes opaque and does not allow the walls to be seen. In order that the fluid may be retained in the female bladder a functionally intact sphincter must be present. As against these, Kelly's method depends on a passive distension of the bladder with air, bleeding does not interfere, and an intact sphincter is not necessary. Kelly's apparatus, moreover, is simple, easily sterilised, easily kept in order, and comparatively inexpensive. By his method the parts are seen directly, while in the electric method they are magnified and distorted so that considerable experience is necessary to enable the observer to form a correct opinion as to the size, shape, and extent of the changes giving rise to the appearances which he is viewing. Finally, Kelly's method allows the ureters easily to be sounded or catheterised and permits the employment of many operative and other methods of treatment.

In comparison with the older methods of examination by the sound and of digital dilatation, either method of cystoscopy possesses great advantages; not only may certain changes, such as ulcers or soft tumours, be easily and fully recognised by visual inspection while they may completely elude detection by the sound or by direct touch, but even when these latter methods are successful cystoscopy gives much more extensive and accurate information as to the conditions present. Further, the method is not more dangerous than the examination by the sound and is much less so than that by the finger.

The normal mucous membrane of the bladder is pale yellowish-red in colour with numerous blood-vessels that form delicate arborescent figures, sometimes anastomosing, scattered irregularly over the surface. As a rule the surface is smooth; occasionally in patches or all over it a delicate network of trabeculæ is seen, due in some cases to temporary contraction, in others and much less commonly to permanent hypertrophy of the muscular bundles. In Kelly's method the posture of the patient and the distension of the organ with air cause anæmia of the vesical mucous membrane, so that the colour appears paler than when seen by the electric cystoscope. On the posterior wall of the bladder a red patch is frequently caused by contact with the end of the speculum and this suction or contact hyperæmia must not be mistaken for a sign of local inflammation.

The shape of the female bladder when passively distended by air is frequently like that of two saucers placed one within the other, the lower wall of the bladder viewed from the inside being concave and the upper forming a downward convexity. The upper and lower segments then appear to be hinged together in a line running across the back of the bladder at about the level of the isthmus of the uterus. Observers are not yet agreed as to the mechanism upon which this shape depends. In the floor of the bladder is seen the trigonum, a triangular area distinguished by its uniform deep red colour from the rest of the mucous membrane. Near each posterior angle of the trigonum is seen a ureteral orifice as a fine point or as a delicate transverse line, two millimetres or so in length, running backwards and outwards and surrounded by a paler area one millimetre broad. The position of these openings varies from eight to 35 millimetres behind the internal opening of the urethra and from 13 to 40 millimetres from each other; commonly a small swelling or papilla is present near each posterior angle of the trigonum and the ureter opens on the swelling, not as a rule on the apex, but on one of the sides, especially the outer. The recognition of the ureteral orifices is as important, and it may be added as easy, as is the examination of the optic discs in ophthalmoscopy. Joining the two ureteral eminences the posterior border of the trigonum frequently forms a well-marked low ridge, behind which the rest of the floor with paler lining extends as a slight hollow to the front of the cervix. At intervals of a few seconds to one and a half minutes the ureteral orifice shows peristaltic movements, the opening becomes wider and sometimes more prominent, and from it is discharged a small stream of clear urine, after which it again closes and remains quiescent. It is difficult to tell whether the two ureters normally excrete together or not; the probability, however, is that each acts independently of the other. In one patient I noted the intervals between the successive escape of jets of urine; from the left ureter two succeeding intervals measured 66 and 87 seconds respectively; from the right, which was noted immediately afterwards, two succeeding intervals measured 54 and 58 seconds. In this patient the orifices of the ureters could not be clearly seen by the unaided vision except when they were actively contracting.

The ureteral orifices vary greatly in appearance in different patients but as a rule are similar in the same patient. Sometimes one orifice is seen to be much larger than the other and this may be due, according to Viertel, to compensatory hypertrophy of the kidney and ureter; sometimes it is caused by the passage of a ureteral calculus. Thus, in one of my patients the right ureteral orifice formed a considerable slit with a grey lumen the lips of which were normal in appearance, the left ureteral orifice was normal in size and appearance, and the right kidney was not enlarged or tender. The patient, a unipara, aged 28 years, was admitted complaining of pelvic pain since her confinement 17 months before. There had been frequent attacks of right lumbar pain for 20 years; the attacks had lasted from a few minutes to several hours; they had never been accompanied by vomiting or dysuria and there had never been hæmaturia. The patient brought an oval calculus which she had passed seven months before. It was of about the size of a French bean and had an annular constriction near one end. On one side of the constriction the stone was fairly regularly rounded, on the other it was smaller and had a flattened end. It appeared to be formed of urates with some oxalates. Sometimes the ureteral orifice "lies dead," undergoing no peristaltic movements; at other times peristalsis may be seen to take place without any discharge of fluid; from this latter sign, according to Viertel, no conclusion can be drawn. In renal hæmaturia and in discharge of pus from the ureter peristalsis is said to be usually absent and the ureter excretes in a slow continuous stream. The passage of a sound or catheter into the ureter is a perfectly easy proceeding in Kelly's method and instruments have been passed as high as the pelvis of the kidney in the search for stones or for the purpose of washing out in certain cases of pyelitis.

My own experience in the use of the cystocope has been confined almost entirely to conditions of the bladder and urethra and the present paper is intended to deal with the bladder only. Among the most frequent indications for cystoscopy may be mentioned catarrhal conditions of the vesical mucous membrane. In acute cystitis the examination is unnecessary and possibly harmful even when it can be carried out. In long-continued and severe catarrh, on the other hand, especially when this is attended by great pain, it is often of great service to be able to see the characters of the changes in the bladder wall, more especially when there is any suspicion that the catarrh is secondary to tumour, stone, foreign body, or ulceration. The signs of catarrh are in the first place redness; this is usually, but not always, present and may depend either upon uniform injection of the capillaries or upon increase in number and size of the larger visible vessels. The redness may be diffused or may be limited to definite spots or patches; occasionally submucous hæmorrhages are seen. The normal smooth glistening appearance is not uncommonly lost, the surface of the mucous membrane becoming more or less roughened or velvety owing to the loss of the superficial layers of epithelium. In some cases swelling of the mucous membrane can be clearly made out and in others there are scattered shining transparent vesicles up to the size of a small pea. This condition has been described by Kolischer as bullous œdema and is not infrequently seen on the mucous membrane covering those parts of the female bladder wall which are adherent to purulent swellings and also in certain cases of cancer of the cervix with implication of the wall of the bladder. The excessive formation of mucus is another effect of inflammation, the secretion varying from a thin fluid that easily escapes to a thick tenacious layer which cannot be completely got rid of by washing. Where stone is present, catarrh of the mucous membrane is often seen in islands or patches, encrusted with phosphates. I was indebted to Mr. A. Lucas for the opportunity of seeing such a case. On August 28th, 1902, we examined a middle-aged woman in the knee-elbow position under anæsthesia. A phosphatic stone of the size of a small walnut had dropped to the apex of the bladder which in this position was the lowest part of the organ. There was patchy redness of the vesical mucous membrane, especially near the base, and on the left side of the posterior wall near its lower part was an irregular white patch of phosphatic deposit.

Sometimes in a severe cystitis a marked papillary inflammation may quickly develop, as in the case of a single girl, aged 23 years, from whom Mr. W. F. Haslam removed through a suprapubic incision a hairpin which had apparently been in the bladder for two months. The hairpin was thickly coated with phosphates and oxalates, and after its removal severe cystitis persisted. I saw the patient six weeks afterwards when the urine was alkaline, offensive, and contained much pus. The bladder did not balloon, but all parts of its mucous membrane that could be brought into view were bright red and granular. The urethra was normal in its upper half; in its lower half it was red and velvety. In this case culture gave a growth of five or six different kinds of organisms, including staphylococcus pyogenes albus and probably bacterium coli.

Ulcers of various kinds are frequently seen, especially about the base of the bladder; these may be catarrhal or due to injury caused by foreign bodies or calculi. Diphtheritic and gonorrhœal ulcers have also been described. Tuberculous affections of the bladder are not uncommon in the female and I have notes of ten cases of very varying degrees of severity. A single patient, aged 19 years, was sent to the General Hospital on Jan. 12th, 1899, as a case of menorrhagia. The supposed menstrual bleeding turned out to be a profuse hæmaturia. The urine drawn off by the catheter was at first clear but towards the end it contained much blood. The cystoscope showed all over the interior of the bladder reddish nodular swellings with soft-looking surfaces; at the base was a whitish, ragged-looking surface with a nodular border. The right ureter was seen as a small bright red pit in the midst of a mass of the growth. The urine from it was clear. The left ureter could not be found. Tubercle bacilli could not be demonstrated in the urine. There was a strong family history of tuberculous disease. The symptoms were said to have begun with pain in the sacrum and hips and the sudden loss of half a pint of blood in one night three months before being seen. This patient died five months later.

In another patient, a single woman, aged 38 years, the cystoscope was of great use in helping to clear up the diagnosis. The patient was complaining of her womb coming down and of dysuria which had existed more or less since the age of 18 years and had been much worse in the last three months. The patient was thin, not anæmic; there was a primary retroversion for the treatment of which the patient was referred to me. The urine, which was of specific gravity 1014 to 1020, contained pus and showed a thick cloud of albumin, probably more than corresponded to the amount of pus present. The bladder held six ounces of urine; on the left side of its floor, just inside the entrance of the urethra, was a small red raised patch. A second similar patch with two or three minute grey specks in it was seen on the trigonum; the right kidney could be felt but was not obviously enlarged. A probable diagnosis of tuberculous kidney was made. The above notes were taken in November, 1900; nearly three years later, on July 25th, 1903, the patient was seen at home; she had had to work hard after last being seen and subsequently was very ill for five or six months; for the last 12 months she had not been able to work but had got up for a part of each day. There was extreme emaciation but no obvious anæmia; a large tender mass filled up the right loin and extended downwards as far as the iliac crest. There was still pus in the urine but no frequency and rarely pain in micturition. There was occasional diarrhœa with mucus in the stools; moist sounds were scattered over both lungs and there was some cough. The patient was now suffering from a right perinephritic abscess and general tuberculosis.

Stone in the bladder is relatively uncommon in the female. When present it cannot always be detected by the use of the sound and in any case the cystoscope presents great advantages over this instrument; by it the presence of cystitis, of ulcers, or of patches encrusted with phosphates is readily seen, while its use is not a whit more painful or risky. Gynæcologists not infrequently meet with stones in the bladder due to perforation of the walls of that organ by ligatures in the process of extrusion. I have seen at least three of these cases, one of which occurred after an operation by myself. Two large pyosalpinges and a fibroid were removed from a woman, aged 47 years; two and a half years later severe pains in micturition began and gradually increased. On March 22nd, 1902, the cystoscope showed in the left lower posterior part of the bladder a small calculus not much larger than a pea imbedded in a depression of the mucous membrane; this was with a little difficulty removed by forceps through a Kelly's speculum and then a ligature encrusted with phosphates was removed from the same depression. Nine months later another calculus of the size of a French bean was removed from the right lower part of the posterior wall.

Foreign bodies as opposed to calculi are found with comparative frequency in the female bladder and Kelly's cystoscope forms a most convenient method of detecting and removing them. The only case of a foreign body that has come under my notice was one in which the end of a glass catheter was broken off and remained in the bladder; the pieces were removed by a lithotomy evacuator before the time when I became acquainted with the method of cystoscopy which we are now discussing.

In certain morbid conditions of the urine the use of the cystoscope is of the greatest service. Thus, for instance, where much pus is present we are enabled to determine whether it comes from one or both kidneys or from the bladder, or whether it is being discharged from a perforated abscess or pyosalpinx. Blood present in the urine may result from many different conditions, vesical, urethral, or renal. Except where the amount is slight in acute cystitis, or where it is due to hæmorrhagic nephritis, a cystoscopic examination is indicated and especially where the bleeding is of long duration or often repeated. Inspection of the bladder usually enables us with ease to determine whether the bladder is the source of the blood or not. It must not be forgotten, however, that occasionally two sources may coexist, one in the bladder and one in the kidney. In the examination of these cases Kelly's method presents a great advantage over the use of the electric cystoscope in that it is feasible even when actual bleeding is going on. Bleeding from the bladder may be due to a large number of different conditions; occasionally it is said to be due simply to diapedesis, as, for instance, in pre-menstrual hyperæmia (Viertel).[*] Sharper bleeding sometimes occurs in active congestion or in acute cystitis; catarrhal and other ulcers, especially tuberculous, foreign bodies and tumours, may all give rise to hæmaturia. Where from the history of the patient a stone or foreign body is suspected to be present the cystoscope should be used in preference to the sound. It is important to remember that in tubercle the passage of blood in the urine is often an early symptom and that an unexpected large hæmaturia is not infrequently the first indication that grave mischief is present; in such cases ulceration has always taken place and when present in the bladder or urethra the ulcer can always be seen.

In certain cases, which have been called bacteriuria, large numbers of organisms are found in the urine with no visible alteration in the vesical mucous membrane. A single girl, aged 19 years, had complained of pain on micturition and increased frequency, especially at night, for 27 weeks; there had been only one menstrual period in the last six months. The urine was cloudy and alkaline, contained a small number of pus cells and an enormous number of bacteria, chiefly motile. The generative tract showed no abnormal physical signs and the cystoscope on two occasions showed no abnormal change in the mucous membrane of the bladder or urethra, with the exception of slight tenderness of the trigonum unaccompanied by increased redness.

In female patients affected with incontinence of urine the use of the cystoscope may give important indications for treatment. In ordinary cases of incontinence in children and young women no abnormal physical signs can be made out about the urethra or the bladder, except that the mucous membranes frequently appear to be decidedly paler than usual. Cystoscopy in these patients is usually easy. The affection appears to depend on a late development of the [illegible] the higher nervous centres with the lumbar cord; clear cases of [illegible] ter 25 years of age. Several of my cases appeared to be markedly benefited by the use of the cystoscope. It is important to remember that nocturnal incontinence in young women may be due to epilepsy; in these cases, again, no abnormal physical signs are present. In another group of cases of incontinence in young women the bladder is found to be redder and more vascular than usual and the neck of the bladder and trigonum markedly tender. The vascularity may be generally diffused over the whole bladder or it may be limited to the trigonum and neck; here the cause of the incontinence is found in the local hyperæsthesia and is not chiefly due to defective control as in the other cases. Belladonna is therefore the indication in one group of cases, and strychnine with iron tonics in the other group. Occasionally a patient comes complaining of incontinence who is really the subject of a grave disease. A single woman, aged 23 years, was seen on August 31st, 1900. She had had constant dribbling of urine for five months, for which time also she had been unable to work. Seven years ago she had been ill in a similar way for two months. The present attack began suddenly while carrying a hod of coal. The urine was constantly dribbling and had given rise to much irritation of the skin of the vulva and neighbouring parts. The patient was examined by the cystoscope without an anæsthetic [illegible] The bladder was contracted; [illegible]eding patch with granular [illegible]; part of the upper wall of the bladder appeared in the form of two folds of mucous membrane of normal colour. The diagnosis in this case was chronic cystitis, probably tuberculous.

Irritability of the bladder in gynæcological patients is another common symptom in the elucidation of which the cystoscope is of great use. Where the irritability is marked the question as to whether it depends upon some condition of the urinary tract itself, or whether it is due to some affection of the generative organs that may also be present, is decided by the presence in the first case of some morbid change in the urine or of decided pain in micturition. In very many cases both pain and alterations in the urine are absent, the vesical and urethral mucous membranes are normal, and the vesical irritability depends upon some affection of the generative organs. Here the cystoscope helps us to understand the mechanism of production of the increased frequency of micturition. In some cases the vesical irritability appears to be caused reflexly, as, for instance, in certain diseases of the mucous membranes, vulvitis, vaginitis, mucous polypi, and sometimes endometritis; where the symptom is reflex the mucous membrane of the bladder and urethra is normal in colour and appearance. In other cases again the bladder and urethra participate in the hyperæmia and increased sensibility of the pelvic organs set up by acute inflammatory changes, such as metritis, pelvic peritonitis, cellulitis, or pyosalpinx. In several patients the bladder has been observed by me to become red almost suddenly during an examination, and it appears probable that increased frequency of micturition may sometimes depend upon vaso-motor disturbance giving rise to such a condition of morbid flushing of the mucous membrane.

While all the conditions just named may themselves suffice to cause vesical irritability, we can only conclude that they do so when the urine and urinary organs are themselves proved to be sound. Not uncommonly an apparently sufficient cause for dysuria is present in the genital tract and at the same time there coexists some morbid condition of the urinary mucous membranes, this latter being responsible for the symptom; thus, for instance, in a case of tuberculous cystitis above mentioned there was also present retroversion of the uterus; in another case of irritability due to chronic catarrh of the bladder in a woman, aged 62 years, there was a small quiescent fibroid in the fundus of the uterus.

One of the most important uses of the cystoscope to the gynæcologist is to enable him to ascertain the relation of the bladder to certain affections of the neighbouring generative organs. Purulent collections, such as pelvic cellulitis, pyosalpinx, or suppurating ovarian tumours, may merely press upon and alter the shape of the bladder without causing any change in the mucous membrane. When, however, adhesions form between them and the bladder the corresponding part of the vesical mucous membrane usually presents more or less thick folds, either normal in colour or swollen and œdematous, sometimes with the formation of scattered clear vesicles, the condition above referred to as bullous œdema. When the abscess has opened into the bladder the orifice may be seen surrounded as a rule by red granulations. After an inflammation adherent to the bladder has run its course cicatricial bands may persist, as in the case of a terti-para, aged 33 years, who had a deep laceration on the left side of the cervix, from which a cicatricial band ran outwards towards the side of the pelvis. There was much pelvic pain attended by frequency and scalding in micturition. The cystocope showed that the bladder and ureters were normal, except that there were several thin, pale bands running transversely on the left lower posterior wall of the bladder; the position of these corresponded with the cicatricial band at the base of the left broad ligament. The urine was normal; a small amount of opaque discharge could be squeezed from the lower end of the urethra.

In carcinoma of the cervix Winter describes progressive changes that take place. When the growth begins to lay hold of the bladder wall the mucous membrane first becomes raised into ridges or folds, usually running parallel to each other. These folds gradually become higher and then the mucous membrane becomes œdematous and small vesicles make their appearance. The changes thus far are just the same as those found in adherent suppurative conditions. Later may be seen small nodules or flat prominences which, by their opacity and the peculiar lustre of their surface, are easily to be recognised as cancer. Hitherto there may have been no trace of cystitis, but when these nodules ulcerate their surface becomes rough and covered with whitish, more or less firmly adherent shreds of tissue, and at this stage there is usually extensive cystitis. In the following case the malignant disease was seen to have already infiltrated the base of the bladder. A quintipara, aged 41 years, had a deep excavated ulcer of the cervix. Under anæsthesia it was found that the growth extended out to the right side of the pelvis and that there was a deep excavation of the anterior wall of the cervix. On the right side of the floor of the bladder was a distinct circular elevation with well-defined edges; the surface was greyish white and opaque in colour; the rest of the interior of the bladder was normal. The cervical ulcer was scraped and the cavity was packed with formalin. The changes above described are usually late and the first formation of folds on the mucous membrane indicates disease implicating the vesico-vaginal septum. The cystoscope may, of course, fail to disclose the fact that a growth has actually begun to invade the wall of the bladder, as was evidenced in the case of a single woman, aged 38 years, who had a diffuse cancer affecting practically the whole length of the vagina. Cystoscopy showed no sign of abnormality of the bladder, ureters, or urethra. The whole vagina with the uterus was removed by operation, but prompt recurrence took place on the left side of the bladder behind the trigonum and led to the death of the patient from suppurative nephritis seven months after the operation. In this patient a vesico-vaginal fistula, which formed ten days after the operation, appeared in the midst of a small patch, about one centimetre square, of red granulations on the left base of the bladder just behind the trigonum.

Thus far I have confined my remarks to the value of Kelly's method of cystoscopy in the diagnosis of certain conditions and symptoms belonging to the urinary system. The specula devised by Kelly have been found by me to be of much use also in the investigation of the condition of the vagina and cervix in young children and in patients of older growth in whom the vagina is narrow. In the treatment as well as in the investigation of many affections of the bladder and urethra Kelly's method is of the most conspicuous service. Various kinds of applications can be exactly made to any part of the mucous membrane that is desired, the curette or a snare may be applied with precision, and foreign bodies or small calculi may often be removed through a speculum of moderate size. Time allows only the bare mention in this place of the application of the method to the diagnosis and management of affections of the ureters and kidneys. In conclusion, I desire to emphasise my opinion that in cystoscopy, especially by Kelly's method, the gynæcologist has been presented with a most valuable addition to his resources. The cystoscope may sometimes enable him to avoid a diagnosis that is entirely erroneous; in very many cases its use amplifies or renders more definite a conclusion correctly formed up to a certain point. Thus, for instance, it enables him to determine the exact relation in which the bladder stands to some disease in its neighbourhood or to understand the precise mechanism by which in a given case increased frequency of micturition or some other urinary symptom is produced. Increase in the number and accuracy of observed facts renders inference more certain and treatment more precise.

GLANDULAR FEVER.

By JOHN W. BYERS, M.A., M.D. M.A.O. (HON. CAUSÂ) R.U.I.,

PROFESSOR OF MIDWIFERY AND OF DISEASES OF WOMEN AND CHILDREN, QUEEN'S COLLEGE, BELFAST; PHYSICIAN FOR DISEASES OF WOMEN TO THE ROYAL VICTORIA HOSPITAL, BELFAST; PHYSICIAN TO THE BELFAST MATERNITY HOSPITAL; AND CONSULTING PHYSICIAN TO THE BELFAST HOSPITAL FOR SICK CHILDREN.

SINCE the middle of the month of November an epidemic has been prevailing in Belfast and in some parts of the north of Ireland, chiefly among children, of a kind which I have not observed before either in private practice or during the years that I was physician to the Belfast Hospital for Sick Children and which seems to me to correspond to the clinical entity described in 1889 by Pfeiffer and termed often by German writers Pfeiffer's Drüsenfieber. Heubner, Dawson Williams, Comby, Donkin, and J. P. West have also contributed largely to the literature of glandular fever. My knowledge is based on 33 cases, some of which occurred in two public institutions, while the others were seen in consultation.

In regard to age, the youngest case was 13 months and the oldest was a female servant, aged 25 years, in a family where the children were attacked; but with the exception of two cases (the one I have mentioned and another, aged 21 years) all were children or young people under 16 years of age. The onset, as a rule, was sudden and the incubation was from five to seven days. As regards the symptoms, in some of the cases the children went to bed in the evening complaining of slight sore-throat; on the next morning there were sharp fever (from 102° to 104° F.) and pain on one side of the neck which was tender on pressure and held stiffly; this was succeeded in another 12 hours by a distinct swelling of the glands beneath, and to the front of, the sterno-mastoid. In the majority of cases a similar enlargement appeared involving the corresponding deep glands of the opposite side of the neck. In the cases seen by me the right side was first affected as a rule. In another group of cases the children complained of little or nothing until the glands of the neck seemed suddenly to enlarge and such cases when seen for the first time in such a condition resembled somewhat aberrant forms of mumps. In the more severe cases headache was complained of as an initial symptom and in a few sickness and vomiting were present and some abdominal pain, but I failed to detect any objective signs of involvement of the mesenteric glands. In none of the cases was the throat in any way affected beyond some slight congestion and in the majority it was natural and showed no abnormal change to explain the slight dysphagia. As to the glands affected, as a rule they were the deep ones under, and in front of, the sterno-mastoid, but in others those in the posterior triangles of the neck were involved. No suppuration occurred in any of the cases and the enlargement of the glands subsided in most of the cases in a week or two from the onset of the attack. In one case the swellings remained longer, the temperature going up and down most of that time in an erratic manner. The majority of the children were convalescent within a week; in some of the severer cases, however, those attacked remained poorly and looked anæmic for a period of from three to four weeks. When the disease entered a house nearly all the children were attacked and in one place two of the female domestics—both adults. No rash appeared in any of the cases nor was there any kidney or other complication, and none suffered from depression except the very severe cases. None died. As to diagnosis, when a case was first seen the adenitis seemed secondary to some throat mischief but after careful examination no sufficient tonsillar or pharyngeal mischief to cause the glandular swellings could be detected; and the presence of other cases in the same house showed that what one had to deal with was an epidemic fever. In the *British Medical Journal* of Dec. 5th, 1903, p. 1492, there is described an "epidemic sore-throat and suppurative mammitis in cows," but in none of the cases seen by me were there any such conditions observed in the throat, and the cases were in groups widely separated and with no common milk-supply. The mild type of cases when seen for the first time with a well-marked unilateral swelling of the neck looked like a form of aberrant mumps, but careful examination showed that the parotid gland was not involved and the children had no pain in closing the jaws or in eating; besides some of the children had previously suffered from mumps. It has been suggested that the disease might be a peculiar form of influenza; but as a rule in recent years when abnormal types of that most protean disorder occurred we were able to diagnose them as being due to the influenza poison from the circumstance that in the same house or locality other ordinary forms of that disease occurred. None of these usual forms of influenza were met with among the cases which I have described or in the houses in which they occurred. I believe the cases I have tried to describe were true examples of that acute epidemic infectious fever in which there is primary enlargement of the lymphatic glands. The poison of glandular fever is probably microbial and the present extraordinary atmospheric phenomena may have provided precisely those conditions necessary for the growth of the infective germ which causes the disease. Some have suggested that infection is through the intestine; in the cases seen by me it looked more as if the invasion was by the throat.

Since writing this article I find that in a family where the children suffered from the ailment I have described two of the adults developed a follicular tonsilitis, but in them, although the glands of the neck were tender, there was no palpable enlargement.

Belfast.

PATHOGENESIS OF DEAFNESS DUE TO CHRONIC NON-SUPPURATIVE MIDDLE-EAR DISEASE.

(SYNONYMS: SCLEROSIS OF THE MIDDLE EAR, DRY MIDDLE-EAR CATARRH, OTOSCLEROSIS, FIXATION OF THE STAPES, OTITIS METIA INSIDIOSA, CHRONIC PROGRESSIVE DEAFNESS, &C.)

BY D. CHALMERS WATSON, M.B., F.R.C.P. EDIN.

IN March, 1902, I published[1] a preliminary note on a method of treatment of chronic non-suppurative middle-ear disease, the essentials of the treatment being the local use of a product of bone marrow combined with appropriate massage and attention to the Eustachian tube. It was pointed out that this treatment had been in many cases more beneficial to the patients than the ordinary treatment consisting in the occasional use of the catheter and various medications to the nose or nose-pharynx. A later record of results with a reference to the principles underlying this treatment and a statement of the limitations to its success were published in August, 1902.[2] Further experience of the treatment has confirmed the favourable impressions recorded in my original paper. This experience has at the same time led to two modifications. The first of them is the use of a clear fluid preparation of bone marrow obtained from the manufacturers and designated "myelocene fluid." The use of this preparation overcomes, at any rate in part, one of the difficulties of treatment reported in my earlier paper—viz., the use of a fatty substance with a high melting point. The second modification is the replacement of the digital vibration described in my first paper by the mechanical aids referred to in the second communication. The present paper is concerned with the pathogenesis of the disease. It is advisable in the first place to define clearly the present opinions of experts on this question. In a discussion on the Aims and Limitations of Intranasal Surgical Procedures in the treatment of Chronic Non suppurative Middle-ear Disease held at the annual meeting of the British Medical Association in 1902, the present position of our knowledge was thus defined by Dr. Urban Pritchard: "In the present state of our knowledge it will be most convenient to group them (cases of chronic non suppurative middle-ear disease) into the following classes: (1) chronic middle-ear catarrh and its results; (2) sclerosis; (3) intratympanic adhesions from acute and subacute non-suppurative inflammations; and (4) mixed cases of the above"—the foregoing classification being regarded as of practical importance from the point of view of treatment. In summing up the President of the Section (Dr. W. Milligan) "considered that the discussion had proved of value in that it had elicited what appeared to be the unanimous verdict of all the speakers, that in *genuine sclerotic catarrhal conditions of the middle ear* intranasal operations were useless and were even harmful, in *chronic non-sclerotic catarrhal conditions of the tympanic mucous membrane*, where inflation improved the patient's hearing power and where some genuine respiratory difficulty was complained of by the patient intranasal surgical procedures were of value and at times markedly so." Now, while these classifications leave some doubt in the mind as to the precise ideas which the writers entertain regarding the relationship of the pathological processes involved in the respective groups, they clearly indicate a belief that at least two distinct pathological processes are at work in the production of chronic non-suppurative middle-ear disease, and further, that the recognition of these two processes is of fundamental importance in treatment. In the latest edition of Politzer's classical work (1902) this differentiation is accentuated by the devotion of a special chapter to "otosclerosis," the synonym of this affection being stated as "proliferous inflammation of the middle ear" (Roosa), otite media iperplastica (De Rossi) and capsulitis labyrinthi, the disease being regarded as one which is in the majority of cases, in its pathology, etiology, clinical features, and treatment, perfectly distinct from, on the one hand, deafness due to "catarrhal adhesive processes" and on the other cases of "nerve deafness."

[1] Brit. Med. Jour., March 22nd, 1902, p. 699.

[2] Ibid., August 30th, 1902, p. 612.

The objects of this communication are: (1) to indicate that the data available for the complete differentiation of more than one morbid process are by no means conclusive; (2) to record facts which lead me to form an opinion as to the unity of these various affections; (3) to point out the importance of settling the query from the point of view of treatment; and (4) to suggest that valuable evidence, and probably essential facts, can be obtained from a too much neglected field of study—comparative pathology. It will here be convenient to indicate briefly the grounds on which two morbid processes are generally differentiated. The clinical reasons may be summarised in the statement that there is met with in practice a not inconsiderable number of cases of deafness due to non-suppurative middle-ear disease in patients who are *not* subject to "colds in the head," the subjective testimony of the patient being supported by the fact that the Eustachian tubes are found unobstructed at the time of examination and the tympanic membrane normal or nearly so. The facts of morbid anatomy relied on are the following.

Many post-mortem examinations have been made—notably the Toynbee collection in the Museum of the Royal College of Surgeons of England—which have revealed as the result of examination with the unaided eye swelling and congestion of the lining membrane of the middle ear with a varying degree of adhesions, thickened tympanic membrane, and alterations in the articular structures. These constitute the group of cases designated hypertrophic catarrh. Other cases have shown a condition which is in great part the antithesis of the foregoing. "On removing the roof of the middle ear affected with the disease the first thing that strikes one is the wideness, whiteness, and dryness of the whole cavity, the contained structures being clearly defined. Fine membranous septa in various parts can be seen and are apparently the atrophied remains of the folds of the lining membrane. A well-marked membrane is sometimes seen running from the tendon of the tensor tympani to the roof. On microscopical examination the layers are atrophied and the distinctive characteristics cannot be made out. The base of the stapes is fixed to the oval window either by calcification, ossification of the ligamentous ring, or by deposit of new-formed osseous tissues upon the inner surface of the foot-plate, and a complete bony union of the wall of the oval window may exist" (Cheatle[3]). These constitute the cases clinically designated as atrophic catarrh. Further, as a result of about 20 post mortem examinations (Politzer, Katz, Habermann, Bezold, and others) there have been described cases which have shown to the unaided eye little or no change in the lining membrane of the tympanic cavity or in the tympanic membrane, the changes present being largely confined to the neighbourhood of the stapes articulation and consisting mainly in bony enlargement. In some cases the sclerosis involved the labyrinth—hence one of the synonyms, capsulitis labyrinthi. The first complete description of this condition was given by Politzer[4] and was based on a series of seven cases that had been observed during life. He has applied the term "otosclerosis" to this condition.

With reference to the foregoing I venture to offer a criticism and before entering into the necessary details I would summarise my position in the following statements. 1. A closer and more systematic study of cases of deafness due to chronic non-suppurative middle-ear disease will lead to a reversal of the opinion generally held as to the absence of clinical indications of catarrh in the group of cases variously described as sclerosis of the middle ear, atrophic catarrh, otosclerosis, &c. Further, the observations necessary to determine this point cannot be made by physicians who only see the cases at rare intervals. 2. If the known facts of morbid anatomy and pathology of cases of chronic non-suppurative middle-ear disease are brought into line with similar facts in the pathology of other mucous membrane and joint structures the impression is forced upon us that the different conditions described in the middle ear can be adequately explained as variants of one morbid process. The grounds for these opinions will be shortly stated.

In a series of over 200 cases that have been closely observed in the last two and a half years in my clinic or private practice I have not met with a single instance where there has not been either (1) a clear history of frequently recurring "colds in the head" of a slight or severe nature, or (2) in patients who definitely affirmed that they were not subject to colds, unequivocal evidence of an [illegible] catarrh in the course of the few [illegible] Further, [illegible] s drawn to [illegible] the point it was affirmed that the condition present was a frequently recurring one but had not ranked in their minds as a common cold. The clinical features referred to are evidence of obstruction to the passage of air into the tympanic cavity by means of a Eustachian catheter to an extent appreciably greater than existed before the onset of the said cold; this was frequently associated with a very slight alteration in the quality of the voice noticeable to the observer and also an alteration in the character of the breathing. It is advisable to draw particular attention to these cases because as many of them had previously been under the care of experts and no special treatment had been directed to the Eustachian tube one is justified in believing that these are cases regarded as "sclerosis of the middle ear" rather than "catarrhal deafness."

The record of clinical facts just stated naturally suggested a study of the known facts of the morbid anatomy of the cases in question with the view of determining how far they justified the recognition of two or more diseases, the practical importance of the inquiry being evident from the different prognosis and treatment of the various conditions. This investigation involved (1) a careful examination of the valuable series of pathological specimens in the well-known Toynbee collection in the Museum of the Royal College of Surgeons of England, the examination being as complete as possible short of actually handling the specimens.

[3] Encyclopædia Medica, vol. iii.

[4] Zeitschrift für Ohrenheilkunde, vol. xxv.

In this examination special attention was directed to a consideration of how the appearances shown and described in the soft tissues, in the bony tissues, and in the local tissue fluids of the ear would compare with those met with in the neighbourhood of other articular structures which are usually described under the heading of chronic rheumatism or rheumatoid arthritis; and (2) special consideration of the facts of morbid anatomy which have led to the recognition of a perfectly distinct disease, "otosclerosis." This disease is one to which increasing importance is being attached as the cause of the impaired hearing in young people in a considerable number of the cases of chronic non-suppurative middle-ear disease. The prognosis associated with it is very bad and little or no treatment is adopted, probably on account of the statement of Politzer that "from the anatomical changes found in the labyrinthine capsule it is evident that our therapeutic efforts must remain fruitless in this form of disease."

Two impressions are derived from this investigation. The first is that in the atrophic group of cases the absence of a detailed histological report of the lining membrane of the middle ear and descriptions of the naked-eye and microscopic appearances of the Eustachian tube makes any conclusion impossible as to the non-identity of this affection with that commonly spoken of as a hypertrophic catarrhal disease. The fact well known to pathologists of the frequency with which an "atrophic" appearance succeeds a "hypertrophic" one in catarrh of mucous membrane makes it probable that this is the explanation of the cases in question. The morbid anatomy of this mucous membrane must be brought into line with that of other mucous membranes. I have recently[5] shown and described an "atrophic" and "hypertrophic" condition of the intestinal mucous membrane which in my judgment is similar in nature to the two processes seen in the ear. With regard to "otosclerosis" a similar criticism applies. The absence of an adequate clinical history and of a histological report on the lining membrane of the middle ear and of a description of the state of the Eustachian tube renders the records incomplete. Further reference to the original paper which led to the recognition of otosclerosis as a distinct disease shows that the patients were old subjects, the respective ages of the seven cases being 77, 86, 75, 75, 50, 86, and 88, the average age therefore being 76. In view of the state of the tissues generally at that period of life too much stress must not be laid on the absence of "reactive phenomena" of inflammation such as are present in younger subjects. A reference to the other three original papers on "oto-sclerosis" to which I have had access shows an absence of unanimity as to the nature of the pathological process. Katz[6] concluded that in his case, a woman, aged 39 years, the condition was a *rheumatic inflammation*. Habermann[7] considered that in his case, a woman, aged 58 years, the disease was secondary to an inflammation of the lining membrane of the tympanic cavity. Bezold[8] regarded the condition as a primary inflammation of the periosteum in the neighbourhood of the stapes articulation. In these records also there is an absence of information as to the state of the aural passages, and in all the records there has been little or no reference to the general medical aspects of the case and no account of the post-mortem appearances of other joints and tissues of the body.

On these grounds, then, I consider that the data at present available do not warrant the recognition of more than one disease. The known facts can be adequately explained by reference to variations in local reaction—e.g., varying amount of exudate and varying degree of formation of new tissues, fibrous and osseous, such as are met with in chronic inflammation in other articulations. The correctness or otherwise of this opinion will not readily be determined from the examination of cases of disease in the human subject. Recourse must be had to comparative pathology, the study of which presents the following advantages. The tissues can be obtained at a relatively early stage of the disease; an adequate examination of the Eustachian tube, middle ear, and tympanic bulla is more easy than in the case of the human subject; and a more complete post-mortem examination of the whole animal can be made than is generally possible in man. I have examined three cases of deafness in dogs and have used as controls two cases where there was no history or evidence of deafness. In the case of two dogs the deafness was stated to exist by the owners, this opinion being shared by the expert veterinary surgeons at the New Veterinary College, Edinburgh, to whom I am indebted for the heads of the animals. The third dog was the property of a medical friend who had observed the onset and steady increase of the deafness. This was submitted to a complete post-mortem examination which revealed gross lesions—viz., chronic endocarditis and chronic intestinal catarrh, with a remarkable condition of stenosis of the intestine. The co-existence of these lesions is of great interest but their consideration is beyond the limits of the present paper, which will deal with the local lesions in the middle ear and Eustachian tube. It is well to emphasise that no conclusions can be drawn from the few facts here presented; my main object will be fulfilled if the attention of investigators is drawn to comparative pathology as a field of study well calculated to advance our knowledge of this department of human medicine.

The results of the examination[9] may be summarised. The Eustachian tubes of the deaf dogs showed distinct evidences of catarrh, the tympanic membranes were more opaque than normal, the mobility of the tympanic membranes and of the ossicles was impaired, the density of the temporal bone was increased, and the lining membrane of the tympanic bulla was extensively congested and thickened (see Fig. 2). A histological examination of the tympanic mucous membranes and also of the lining membrane of the tympanic bulla showed marked thickening—sclerosis—with increased vascularity. Special attention is drawn to the histological appearances of the Eustachian tube seen in Fig. 4. They suggest a query as to the soundness of the principle of the treatment of such cases by the use of Politzer's bag. This deafness can be explained by a diagnosis of "chronic hypertrophic catarrh"; at the same time the increased density of bone and overgrowth of fibrous tissue also justify a diagnosis of "otosclerosis." The amount of exudate and of adhesions was less than has frequently been found in cases of chronic catarrhal deafness in the human subject; further, the sclerosis of bone was diffuse throughout the temporal bone and was not mainly localised to the inner wall of the middle ear, as in cases of otosclerosis. But we know that similar variations are seen daily in other articulations in cases of chronic rheumatism where they are probably rightly regarded as mere variants of one pathological process and in the absence of further facts we are, I

believe, justified in so regarding the aural cases. The appearances in the soft tissues and in the bony tissues of the ear are those of chronic inflammation; they represent the manner in which these tissues respectively react to irritants of bacterial origin. In recent years it has become more and more evident that the only theory that allows the full meaning of inflammation to be grasped is the broad biological conception which recognises in inflammation an adaptive, protective, and reparative tendency common to the reactions to injury among all animals. Inflammation brings into operation a number of factors to counteract harmful agents, to protect the organism at large, and *to effect* healing. The common mode of origin, the similarity of the changes (though combined in different proportions) and the evident tendency of inflammatory processes to protect and to repair fully justify the teaching that *inflammation is essentially an adaptive, protective,* and reparative process, a means of self preservation. Yet it must not be forgotten that the mechanism of defence and preservation is far from perfect; the exudate may possess but little bactericidal power; the phagocytes may be powerless or the bacteria may multiply freely within them; extensive destruction of tissue may occur before the virulence of the bacteria is neutralised; the fixed cells may form imperfect material for repair or multiply in excess; the resulting cicatricial tissue may lead to serious functional disturbances (Hektoen-Riesman). A consideration of these points explains all the clinical and pathological features of cases of chronic non-suppurative middle-ear disease. The attention of aurists is only directed to these cases because the resulting local reactions which are mainly of a protective nature have, as it were accidentally, induced serious functional disturbances. With regard to the causal agents of the inflammation nothing definite can be said. We know that the common causes of injury to tissue are bacterial. With regard to aural disease it is known that the clinical picture of acute otitis media can be produced by the pathogenic activity of at least three different bacteria—streptococcus pyogenes, staphylococcus pyogenes aureus, and the pneumococcus. It is conceivable that the chronic forms of inflammation may be induced by the attenuated activity of the same bacteria. In other departments of medicine we find suggestive facts. The gonococcus *or its toxins induce at one time an acute local* suppuration, at another a chronic articular non-suppurative inflammation. The bacillus typhi can induce suppuration; it also occasionally induces a condition of joints clinically and patholo [illegible] om rheumatoid arthritis. Again, [illegible] the large joints has been very co[illegible] of dysentery in Europe (Davidson). And perhaps even of greater interest from the point of view of "otosclerosis" is a reference[10] to the attenuated *form of staphylococcus osteomyelitis recognised* by surgeons as a distinct clinical and pathological entity. While I have just stated that in my opinion we have to deal in all cases of chronic non-suppurative middle-ear disease with a local reaction to bacterial invasion *viâ* the Eustachian tube, we must remember the possibility of the co existence of an infection by the blood stream. This is probably a factor in many cases, more particularly in those in which there are clinical manifestations of disease usually designated as rheumatism *or gout.*

THE OPERATIVE TREATMENT OF HERNIA IN INFANTS AND YOUNG CHILDREN,

ILLUSTRATED BY 114 CONSECUTIVE CASES.[1]

BY ROBERT CAMPBELL, B.A., M.B. R.U.I., F.R.C.S. ENG.,
SURGEON TO THE BELFAST HOSPITAL FOR SICK CHILDREN.

WHEN the secretary of this society asked me to read a paper at one of our meetings I chose the subject of the treatment of hernia in infants and young children because it is one in which the majority of the members are more or less interested and because it is a condition in the operative treatment of which I have had considerable experience. In considering the question it is necessary for us to bear clearly in mind that the essential cause of hernia in children is the presence of a patent funicular process, and that, therefore, any method of treatment which aims at curing the deformity must secure the obliteration of this peritoneal pouch. Now, if we consult the text-books on surgery we find that most of them contain the statement that hernia in children is curable by a truss and that a steel spring truss covered with rubber is the most useful form to apply. If, however, we inquire a little more closely into the matter we find that it is not so simple as it at first sight appears. For instance, Mr. W. McAdam Eccles, a strong advocate of the use of trusses, in discussing the question in his monograph on hernia, admits that "the permanent closure of the processus vaginalis will be obtained in the majority of cases only after the continuous action of a steel spring truss over a period of some years" and that "the truss, carefully adjusted, must be worn by the child continually day and night, sleeping and waking, crying and peaceful." The endeavour to carry out this line of treatment will plainly involve the expenditure not only of much care and patience but also of a considerable sum of money in the purchase and repair of appliances. Truss treatment will therefore have to be confined to the children of the well-to-do. If, however, the result of the treatment were the permanent cure of the deformity we might be inclined to overlook the question of care and expense. But does the use of a truss secure this with any degree of certainty? I think not. It is true that in many cases the hernia ceases to descend but it is also true that in most cases the truss does not bring about the closure of the funicular process, but merely causes a narrowing of its neck, so that the patient goes through life with a peritoneal pouch ready at any time to receive a loop of bowel on any unusual increase of intra abdominal pressure. Coley, for instance, found on analysing a large series of cases of hernia in adults that about one-third of these had been treated for hernia in childhood by the application of a truss and there is a strongly growing belief among operating surgeons that all oblique herniæ in adults are due to the presence of a congenital sac. Against the use of trusses we may therefore fairly urge that it is a tedious, difficult, and uncertain method of treatment and that during its employment the patient is constantly running the risk of strangulation occurring. I am consequently of opinion that all herniæ in children should be treated by operation, with the possible exception of small easily controlled herniæ in the children of well-to-do parents; and this opinion is based on the following reasons: (1) by operation the funicular process is completely removed and the essential cause not only of herniæ in children but also, according to recent opinion, of all oblique herniæ in adults is got rid of; (2) the time occupied in curing a hernia by operation is about a fortnight as compared with three years by the use of a truss; (3) the cure by operation is almost certain to be permanent; and (4) the risk of operative treatment is certainly not greater than the risk of death from strangulation during the use of a truss.

My advocacy of operative treatment is based on a personal experience of 114 consecutive cases of radical cure in children. This series includes both strangulated and non-strangulated cases; and I may be permitted to dwell on a few points of interest in reference to them. All the cases were in[illegible]. Over two-thirds of them were on the left [illegible] and only five were females. The age [illegible]ion varied from three weeks to ten years. The two youngest patients, aged 21 and 24 days respectively, were operated on for strangulation, while the youngest child on whom I have operated apart from strangulation was six weeks old. In about nine out of every ten cases the sac was not continuous with the tunica vaginalis testis. The contents of the sac were generally small intestine; omentum was rarely seen; in only one case did the bladder present; while in ten cases the cæcum and vermiform appendix together with the lower end of the ileum were found. The strangulated cases numbered eight; all were under two years of age. The strangulation was in no case very acute but a marked tendency was observed to the formation of subserous hæmatomata between the layers of the mesentery and on the surface of the bowel. These were sometimes as large as a marble and gave rise to difficulty in reducing the gut.

I shall now turn to the operation, its risks, its complications, and its results. In children under two years, unless the hernia is very large and the walls of the inguinal canal in consequence are much stretched, a modified Mitchell Banks operation is performed. In older children and in all cases of large herniæ Bassini's operation is selected. The ligatures for the neck of the sac and for the blood-vessels are composed of catgut hardened in formalin and boiled. I have employed catgut prepared in this way for over five years and I was not aware that I was using any novel form of suture or ligature until I saw some correspondence on the subject two years ago in the *British Medical Journal*. An objection has been advanced against it that it is not sufficiently strong. I have been told by one of our gynæcologists that it cannot be relied on to secure an ovarian pedicle. But I believe that if good catgut be selected, that if it be properly prepared, and that if it be allowed to cool, and therefore to harden, after it has been boiled, it possesses sufficient strength for all ordinary purposes. I have tied the brachial, the femoral, and the popliteal arteries with it and have had no reason to repent my reliance on it. Silk I have long ceased to employ on account of its tendency gradually to make its way out months after the operation.

In the majority of the operations I have worn thin rubber gloves and I frequently, especially when demonstrating the operation to students, wear over the head a square piece of sterilised gauze split into two tails at either side, the anterior two being tied behind the neck and the posterior two being brought forwards over the mouth. This latter precaution I adopted after seeing operators and their assistants now and again during an operation in which they were much interested shed showers of dandruff into the wound, and also from the observation that some people cannot speak to you without spitting into your face. The "wipes" employed are of sterilised gauze wrung out of boiling saline solution and the dressing consists of dry sterilised gauze and wool held in position by several turns of a spica bandage on either side and also by a looped perineal bandage which includes, and exercises gentle pressure on, the scrotum. This bandaging of the scrotum I consider to be of great importance as it entirely prevents that œdema of the scrotum which is so frequently seen if a spica bandage only be employed. A piece of jaconet with a hole for the penis is fixed over the dressing with two or three turns of a bandage.

As regards after-treatment, the child is kept in the recumbent position by straps round the shoulders, the legs are lightly secured to sandbags by straps and buckles, and a urine glass is placed between the thighs, the penis being fixed in it by a plug of cotton-wool. In this connexion I might remark that it is better not to circumcise a child before operating for hernia as the long prepuce acts as a guide for the urine. After the first day the child gets his ordinary diet. The skin sutures are removed on the seventh day, the wound is covered with collodion, and in hospital cases the child returns home on the ninth or tenth day, instructions being given not to allow him to get on his feet until a fortnight has elapsed from the time of operation.

Turning now to the risk of the operation we find that it is practically *nil*. Not a single death has occurred in the whole 114 cases. The complications also have been exceedingly few. Bronchitis has been met with twice, both patients being children affected by rickets; suppuration, necessitating the opening up of the wound, occurred in one case. I might here remark that nothing militates more against a successful permanent cure than sepsis. Accumulation of blood clot in the wound requiring the removal of two sutures occurred in one case. The blood in these cases

[1] [illegible]lster Medical Society on Dec. 3rd, 1903.

is venous, and its effusion is, I think, accounted for in this way. During the separation of the sac some of the smaller veins of the spermatic plexus get torn but do not at first bleed to any appreciable degree. If, however, the inguinal canal be sewn up so tightly as to constrict the veins then the blood is poured out in considerable quantity.

The results of the operation are most satisfactory. Nearly all the patients have been seen six months after operation and in only one case was there any tendency to recurrence and this simply amounted to slight bulging of the abdominal wall opposite the internal ring.

I think that the facts which I have put before you are sufficient to show that the operative treatment of hernia in infants and young children is the quickest, easiest, and most certain means of dealing with the deformity and that the use of trusses should be the exception and not the rule.

Belfast.

TUBERCULOSIS OF THE TONSILS IN CHILDREN.

BY L. KINGSFORD, M.D. EDIN., D.P.H. CANTAB.

IT is now recognised that tuberculosis of the faucial tonsils instead of being, as was formerly supposed, a disease of great rarity is one of comparative frequency. Owing to the difficulty of recognising the disease by the naked eye its diagnosis and frequency can be ascertained only by the aid of the microscope and by inoculation experiments. A considerable number of observers, amongst whom Straussmann[1] Kruckmann,[2] Schlenker,[3] Ruge,[4] and Walsham[5] with the microscope, and Dieulafoy[6] by inoculation experiments are perhaps the chief contributors, have recorded a large number of cases of tubercle of the tonsils in adults. But so far as I can ascertain only two observers, Friedmann[7] with the microscope and Latham[8] by inoculation, have confined their attention to the tonsils of children. The usual method of infection of the tonsil is by tuberculous sputum or by the blood stream secondary to tubercle in the lungs or elsewhere. The former method is more common in adults owing to the greater frequency of phthisical cavities, but in children the more usual infection is probably by the blood stream. Primary infection of the tonsils is, however, not infrequently met with in children and in such cases the tonsils show either the only evidence of tubercle in the system or else lesions of an oder date than any lesions elsewhere. The primary infection may be from infected food lodging in the crypts or from inhaled bacilli settling on the fauces and there are no means by which one can distinguish the source of the infection. In feeding experiments with animals the tonsils have sometimes become tuberculous, but as no record has been made of any similar infection by inhalation experiments it is probable that most of the primary tonsil cases are due to food. On the other hand, if inhalation tubercle occurs at all in the tonsils it would be more likely in early childhood when mouth breathing is so common.

With reference to the frequency of the disease, Friedmann, out of 145 post-mortem and operation cases, found evidence of tubercle 17 times, 12 of these being cases primary in the tonsils, whilst Latham by inoculation demonstrated the presence of tubercle bacilli in seven out of 45 operation and post-mortem cases. It has been found by Schlenker and Wright[9] that occasionally tubercle bacilli were present in the adjacent cervical lymphatics when the tonsils were free, and it seems reasonable to conclude that in these cases the bacilli may have passed through the tonsils without injuring them. Two years ago I cut sections of, and examined microscopically, the tonsils removed post mortem from 17 children of ages varying from four months to nine years. All these cases showed some enlargement of the cervical glands, which in 11 were obviously tuberculous. The tonsils were obtained from the East London Children's Hospital, Shadwell, and my best thanks are due to the then pathologist to the hospital, Dr. Olive Rivière, to whom I am indebted for the tonsils and for permission to use the post-mortem notes. I will give a brief description of the post-mortem conditions and of any microscopical changes found in the tonsils.

CASE 1.—The patient was three years of age. The post-mortem condition was as follows. There was marked caseation of the thoracic and abdominal glands with acute general miliary tuberculosis. With regard to the tonsils the right one was enlarged and scarred. Microscopically there were a few giant cells and some fibrosis but no tubercle bacilli were found. Apparently the tonsil here shared in the general infection.

CASE 2.—The patient was four years of age. The post-mortem condition was as follows. There were early caseation of the bronchial and mesenteric glands and early general miliary tuberculosis. As to the tonsils, the right one microscopically showed a few giant cells with some surrounding fibrosis. There were no tubercle bacilli. Probably here again the tonsil shared in [illegible]

CASE 3—This patient was [illegible] mortem condition was as foll[illegible] all the thoracic and some of the mesenteric glands. There were also present tuberculous broncho-pneumonia, miliary tubercles in the spleen and the kidneys, and commencing caseation of the cervical glands. With regard to the tonsils, the right one showed superficial ulceration and microscopically some giant-cell systems with some fibrosis and necrosis but no bacilli. The left tonsil showed great numbers of tubercle bacilli grouped together in some of the more superficial follicles, but no giant cells were detected. In this case the oldest lesions were those of the thoracic glands and the tonsils were probably infected by the sputum.

CASE 4—The patient was aged eight months. The post-mortem condition was as follows. There was a chain of caseous and breaking down glands extending from the left tonsil to the clavicle; there were also some tuberculous tumours *in the cerebrum with acute general miliary* tuberculosis. A careful examination of the tonsils failed to detect any trace of tubercle. The infection had evidently taken place through the pharynx and may conceivably have entered by the pharyngeal tonsil which was not examined.

CASE 5—The patient was two years of age. The post-mortem condition was as follows. There were old caseation of the thoracic glands and general tuberculosis. The left tonsil had very large crypts and microscopically showed typical giant-cell systems. No bacilli were found. The right tonsil was hypertrophied but not tuberculous. The infection was evidently secondary to the thoracic glands, probably by the blood stream.

CASE 6.—The patient was aged one year. The post-mortem condition was as follows.. There were bronchiectasis and fibrosis of both lungs and scattered caseous tubercles, slight caseation of the tracheal and mesenteric glands, early general miliary tuberculosis, and some caseation of the cervical glands. Both tonsils contained giant-cell systems and in the right one some tubercle bacilli were present in the giant cells. Here the infection was secondary, probably by the blood stream.

CASE 7.—The patient was five years of age. The post-mortem condition was as follows. There was broncho-pneumonia but there were no visible tubercle lesions in the body. Both tonsils were hypertrophied but otherwise were healthy.

CASE 8.—The patient was aged four months. The post-mortem condition was as follows. There were old tuberculosis of the left bronchial and tracheal glands, tuberculosis of the left lung, and some generalised tuberculosis. There was one firm caseous cervical gland on the left side. Both tonsils were quite healthy.

CASE 9—The patient was aged one year. The post-mortem condition was as follows. There were old tuberculous disease of the right lung and old caseation of the tracheal and bronchial glands. All the cervical glands on the left side were enlarged, the upper ones containing miliary tubercles and those near the clavicles showing caseation. Both tonsils were healthy.

CASE 10.—The patient was aged nine years. The post-mortem condition was as follows. No pathological changes were met with beyond some engorgement of the lungs, perisplenitis, and enlarged submaxillary glands. Both tonsils were hypertrophied and showed inflammatory exudation but there was no evidence of tubercle.

[9] Wright: New York Medical Journal, April, 1900.

CASE 11.—The patient was aged two years. The post-mortem condition was as follows. There were old caseous thoracic glands with acute general tuberculosis. Both tonsils were healthy.

CASE 12.—The patient was aged one year. The post-mortem condition was as follows. There were old tuberculous thoracic glands with acute general tuberculosis and some miliary tubercles in the right cervical glands. The left tonsil was hypertrophied and under the microscope typical giant cells were seen. Giant cells were also present in the right tonsil but no bacilli were found. The infection here was secondary to the tubercle of the thoracic glands.

CASE 13.—The patient was aged 11 months. The post-mortem condition was as follows. There was tuberculosis of the left lung which had spread from caseous left tracheal and bronchial glands; there was also acute general tuberculosis. There were caseous nodules in the submaxillary and cervical glands on both sides. Both tonsils were normal in size. The right tonsil contained a few not very typical giant cells. The left tonsil on section showed a small apparently caseous area, which under the microscope was seen to be composed of many typical giant-cell systems involving several of the follicles and a surrounding area of necrosis. Tubercle bacilli were present in some of the giant cells. Owing to the fairly advanced tuberculosis of the left tonsil and to the fact that it was also the left cervical, left tracheal, and left bronchial glands that were chiefly affected, it may possibly have been the case that the original entry was through the tonsil.

CASE 14.—The patient was two years of age. The post-mortem condition was as follows. There were old caseation of the right tracheal glands and old fibrosis with some caseation of the right cervical glands with acute miliary tuberculosis. The right tonsil was enlarged and the left was atrophied but otherwise healthy.

CASE 15.—The patient was four years of age. The post-mortem condition was as follows. There were very old caseation of the right tracheal glands and recent tubercle of the intestines and meninges. Both tonsils were quite healthy.

CASE 16.—The patient was three years of age. The post-mortem condition was as follows. There were caseous thoracic glands, especially on the right side, and cavities in both lungs, intestinal ulceration with some caseation of the mesenteric glands, and caseous masses in the brain. The cervical glands were enlarged and above the right clavicle there were some very old fibro-caseous glands. Both tonsils were healthy.

CASE 17.—The patient was aged one year. The post-mortem condition was as follows. There was caseation of the thoracic and mesenteric glands. There were cavities in the right lung, intestinal ulceration, and general tuberculosis. One cervical gland was caseating. Both tonsils were small but healthy.

Of these 17 cases, therefore, seven showed evidence of tuberculosis of the tonsils when examined microscopically but only three exhibited any naked-eye evidence of the disease. Of these three one showed ulceration, another scarring, and the third a caseous spot. Out of five cases where the tonsils were hypertrophied only two showed tubercle, the remaining tuberculous lesions being found in tonsils of normal size. Case 13 is the only one having any claims to consideration as a primary tonsillar infection and that case is very doubtful. The remaining cases were certainly all secondary to lesions elsewhere, the infection of the tonsils having been by the blood in five and in the other case probably by the sputum. In Cases 4, 8, and 14 where at the necropsy it seemed likely that the bacilli had entered originally through the tonsils no evidence of tubercle could be found in them. The parts of the tonsils which were the seats of the lesions were usually the lymphoid follicles not far from the epithelial surface, but in no instance was I able to trace bacilli in from the crypts or surface of the tonsils. With regard to the ages of the cases it will be seen that two occurred in the first year of life, two in the second, and one in each of the third, *fourth*, and fifth years. Goerdeler[10] has met with several under six months and Latham one at the age of three *months*.

It has surprised me on investigation to find how few cases of tubercle have been recorded in hypertrophied tonsils removed by operation. Purves Stewart[11] described one case in 1895 and Friedmann found one case out of 54 that he examined, but Walsham and Wright out of a large number of cases did not come across a single instance. I cut sections of the hypertrophied tonsils of two operation cases which had enlarged cervical glands but found no trace of tubercle in either case. Altogether, some 200 cases seem to have been examined microscopically and only two cases of tubercle were found. Dieulafoy was more successful by inoculation as he found tubercle in eight out of 61 cases by this method, but since he did not in his experiments exclude any tubercle bacilli which might have been present free in the crypts his results are not quite so valuable as they would otherwise have been. It seems fairly reasonable to conclude that if hypertrophied tonsils removed by operation are tuberculous the infection has entered by those tonsils, for otherwise symptoms of serious disease could hardly fail to be noticed.

The belief which has of late years steadily been gaining ground—namely, that the tonsils are one of the most important channels by which the tubercle bacilli enter the system in childhood—has many supporters, amongst them Woodhead,[12] Latham, and Aufrecht. Indeed, Aufrecht[13] goes so far as to say that this happens in practically every case of tuberculosis at any age. He contends that the bacilli pass through the tonsil to the cervical glands and from them directly into the blood stream. It seems hardly likely, however, that they would frequently pass through the tonsils without leaving behind some lesion which, by its chronicity, age, or extent (compare Case 13), would give some idea of its primary nature. In view of the small number of primary tonsil cases described compared with the total number of cases investigated I do not think we are justified in going further than to say that the tonsil is a recognised channel of infection, and the evidence seems strongly against Aufrecht's contention.

From these cases and from the investigations of others the following conclusions may reasonably be drawn: (1) that tuberculosis of the tonsils, especially in cases with tubercle elsewhere, is fairly common, though the disease is usually latent; (2) that tonsil tuberculosis may be primary and, indeed, the only seat of the disease in the system, though this is rarely the case; (3) that the usual method of infection is by the blood stream in children from an older focus elsewhere; (4) that infection also may occur by the sputum in children; (5) that when the tonsils are tuberculous the corresponding cervical glands become affected; and (6) that sometimes where it is probable that the infection entered through the tonsils they were quite healthy but the adjacent cervical glands were tuberculous.

PRELIMINARY NOTE ON

THE PROPHYLACTIC ACTION OF GARLIC AGAINST TUBERCULOUS DISEASES.

BY DR. GIULIO CAVAZZANI.

AFTER the favourable results obtained in treating pulmonary phthisis by means of garlic, which I published for the first time in 1901[1] and which were confirmed later by further statements of mine and of others,[2] I thought it might be useful to see if garlic would also have a favourable effect on the course of other tuberculous infections in animals for experimentation and, eventually, if it would demonstrate a specific action against phthisical diseases. The question is of such vital importance that, having obtained favourable results from the first researches, I think it is my duty to make them known immediately in order to provoke discussion and to stimulate research by which if my purely objective statements were confirmed, a therapeutic and civil problem which is perhaps the greatest one of our age would be solved.

Donti: Contrib. alla Cura Ra[illegible] Gazzetta Internazionale di Medicina, 1903.

About the end of June, 1903, I took eight guinea-pigs, six of which had been submitted to a preventive treatment for a fortnight, each swallowing daily 0 06 gramme (one grain) of garlic juice. After having dried and powdered expectorated mucus from tuberculous patients I insufflated a small quantity of this material into the larynx of each guinea-pig. The animals so treated were kept for two days in a room impregnated with the same powder. Two guinea-pigs were kept as controls throughout the experiment. Three of the remaining six were given the above-mentioned quantity of garlic for a fortnight and the other three were given a similar amount till the end of September. I killed the animals in the first week of October.

The results of the necropsies were that the abdominal organs and the lymphatic system of the two guinea-pigs used for control were completely filled throughout with tuberculous formations in different stages of development. The microscopic examination of some tubercles proved the presence of Koch's bacillus. In the bodies of the three animals which had been treated with garlic for one month I found from 10 to 20 small tubercles, some of them in the liver and some in the spleen. The examination of the tubercles did not reveal the presence of Koch's elements, but instead it showed the presence of numerous fibres of young connective tissue. In the bodies of the other three guinea-pigs, those which had been treated with garlic up to the end of the experiment, I could find no tuberculous formations though the most minute examination was made. The small number of animals used in the experiment forbids the drawing of conclusions.

If these results should be confirmed by further researches, which I have already begun, it would be proved that garlic prevents at least guinea-pigs from contracting tuberculous diseases through breathing the germs. As this seems to be the commonest way of contracting phthisis, and if we may consider animal pathology in the same light as human, it might mean the discovery of a method for preventing consumption.

Venice.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES OF A CASE OF HÆMATURIA DUE TO THE HÆMORRHAGIC DIATHESIS.[1]

BY H. B. A. PEARSON, L.R.C.P. LOND., M.R.C.S. ENG.

THE patient, who is an unmarried female, 40 years of age, has been suffering from an attack of hæmaturia with variable losses of blood ever since Christmas, 1901. Her urine is acid in reaction; on standing it looks like beef-tea with sediment at the bottom and, as would be expected, it contains albumin. Under the microscope blood cells in large numbers and blood casts are seen. During the attack she has suffered from pain in the region of the right kidney, [illegible] passing down in the direction of the left ureter to the bladder, giving an impression that for the first 12 months the right kidney only was in fault. Menstruation is regular but prolonged to eight days; 20 diapers are used and become well soaked. Bright coloured blood has been vomited but there has not been any symptom to suggest either hæmoptysis (there is no cough or expectoration) or hæmatemesis due to gastric ulcer, or even a varicose condition of the throat. Bright-coloured blood has been passed from the bowel but like so many of her sex the patient suffers from constipation and the passage of hardened fæces over the mucous membrane would be sufficient to account for this. She suffers from a rash, pinkish red in colour, fading into yellow, following the lines of the lower inter costal nerves. This is probably nervous in origin and traceable to the two kidneys as it occurs on both sides. She has not had any rash of a petechial or purpuric character, neither has she suffered from epistaxis, hæmatomata, or swelling in the joints due to hæmorrhage.

The family history is as follows. The patient's paternal grandmother died suddenly at the age of 28 years from hæmorrhage. The father, son of the above, died at the age of 60 years from hæmorrhage into the brain or meninges after an illness of 24 hours' duration; he had no brothers, but his three sisters all died suddenly under the age of 30 years from hæmorrhage; one of the sisters had three children, all of whom died young from hæmorrhage. The patient, his daughter, lost one brother at the age of 15 years from heart disease and hæmorrhage; one sister, aged 24 years, died suddenly with vomiting of blood, and another sister, aged five months, bled to death. She has five sisters living, all in good health except that one of them in her confinements has ante- and post partum hæmorrhage. She has one brother living, in good health and not liable to hæmorrhage. One of her sisters lost one boy, aged one year and eight months, one girl, aged two years and seven months, and one girl, aged five years, from hæmorrhage. Her mother's family was healthy and not liable to hæmorrhage. The patient's first attack of hæmaturia occurred in 1894; it was caused by mental worry due to the death of her father and lasted for eight months. The second attack came on in 1899, after the death of a niece, and lasted for three months. She has always suffered from vomiting on the slightest provocation. She has had measles, whooping cough, pleurisy, and congestion of the liver. The cause of the hæmorrhage is evidently associated with some abnormal condition affecting the kidney or its hilum, as I have washed out the bladder on three different occasions with negative results.

This class of case seems to be rare. According to American records not one case was reported in ten years, but Grandidier, on the other hand, has collected references to a considerable number, of whom only a small minority reached maturity. The family history of this patient is at variance with the doctrine currently taught—namely, that the females usually transmit the diathesis to their male children. Evidently in this case the paternal grandmother transmitted it to her three daughters who all died from it under the age of 30 years, and through her son to his daughters. This family history is certainly worth studying and also being recorded. The patient herself personally does not give any clue as to what she is suffering from and is able to carry on her occupation. Hot articles of food, however, increase the hæmaturia, so she is practically limited to food taken cold. She feels better in cold than in hot weather.

New Wandsworth, S.W.

OPERATIVE TREATMENT OF A PERFORATED GASTRIC ULCER.

BY JOHN H. TONKING, M.B. LOND., L.R.C.P. LOND., M.R.C.S. ENG.,

SURGEON TO THE WEST CORNWALL MINERS', WOMEN'S, AND CHILDREN'S HOSPITAL.

THE patient whose case is now described is a single woman, 39 years of age. For about 18 months she had suffered from symptoms of gastric ulcer and usually confined herself to a special diet but with occasional lapses, one of which occurred on the evening of Oct. 21st, when she partook of potted tongue. Early on the following morning she was awakened by violent internal pain which was agonising when I saw her at 9 A.M. Her abdomen was then absolutely rigid but there was no vomiting. I thought it advisable not to give morphine but I administered one-thirtieth of a grain of nitrate of strychnine hypodermically and communicated with Dr. Frank Hichens of Redruth, who saw the patient with me at 11 A.M. and concurred in the diagnosis of perforated gastric ulcer. Morphine (a quarter of a grain) was then given and the patient was removed to the West Cornwall Miners', Women's, and Children's Hospital at Redruth, a distance of three miles. Here at 2 P.M.—i.e., within 12 hours of the perforation—Dr. W. Blackwood administered ether and I with the help of Dr. Hichens cut down on the stomach. The anterior wall midway between the lesser and the greater curvatures was covered with inflammatory lymph and the abdomen was full of turbid serum, a large quantity of which escaped. At this stage the patient's pulse, which had been 120 per minute at first, rose to 132 and became very weak. An ounce of brandy and one and a half ounces of hot coffee were thereupon given by the rectum as well as one thirtieth of a grain of strychnine hypodermically. The perforation was about as large as a pea and was situated in the centre of an induration which from its size and thickness (it occupied about the extent of a five-shilling piece) suggested a new growth. Much difficulty was encountered in suturing the perforation, many of the silk sutures cutting out, but at last it was closed with four Lembert sutures and the whole induration was tucked in and secured by a few more Lembert sutures. The surface of the stomach was wiped with gauze swabs, as much fluid as possible was removed, a drainage-tube was inserted, and the wound was closed with silkworm gut. The patient was fed by nutrient enemata until the 28th when her bowels were moved by calomel followed by a laxative enema. On this day one drachm of whey was given by the mouth every hour and on the following day one drachm of peptonised milk was given every hour. The course of the temperature showed few special features, never falling below 97° F. and not rising above 100° except on Oct. 31st and Nov. 2nd. Hypodermic injections of one-thirtieth of a grain of strychnine and one-hundredth of a grain of digitalin were given several times a day from Oct. 31st to Nov. 5th inclusive. The convalescence, which was long and tedious, was interrupted by an attack of catheter cystitis and about Nov. 19th by an abscess bursting in the position of the drainage tube; after this, however, she improved rapidly and left the hospital as recovered on Dec. 22nd. Since the operation there has been a marked change for the better in her gastric symptoms and she is no longer troubled with the pain and pyrosis from which she formerly suffered.

---

[1] The patient was shown at a meeting of the South-West London Medical Society in April, 1903. See THE LANCET of April 18th, p. 1105.

Camborne, Cornwall.

A CASE OF CONCURRENT ATTACK OF URTICARIA AND MALARIAL FEVER.

By DR. GEORGE PAPAKOSTA,

GREEK ARMY MEDICAL SERVICE.

THE patient in this case was a sergeant of infantry, 26 years of age, who had always been in good health until two years *previously* when he suffered very much from malarial fever of an obstinate character. He was then serving in Missolonghi and for a great while he took quinine which provoked hæmaturia. Again in Corfu in 1902 he was twice attacked with the same fever, of which he was cured, and he remained well till the end of November, 1903, when for four days he felt himself much out of sorts and on the morning of Dec. 2nd he was admitted to the military hospital complaining of shivering, headache, giddiness, vomiting, and diarrhœa. His temperature was found to be 103·4° F., his tongue was furred, his liver was apparently normal, his spleen was rather enlarged, and all over his body and face there was a general red eruption of urticaria which at first gave rise to a suspicion that he might be suffering from measles. In the afternoon his temperature fell to 99·1°, the vomiting and diarrhœa ceased, the eruption disappeared, and towards night his condition became good and he perspired freely. On the morning of the 3rd he had no fever but in the afternoon he had a fresh attack of fever and the former symptoms reappeared and lasted till the following day when his temperature fell and the urticaria with the associated symptoms disappeared. He was not given quinine on account of the hæmaturia, but on the morning of the 5th he was again seized with shivering and his temperature rose to 101°. I immediately injected 15 grains of quinine. The fever continued till the next evening but without any recurrence of the eruption or of the other symptoms. The man is now fairly well although weak. Examination of his blood showed that the plasmodia of Laveran were present.

Corfu.

GLOUCESTER INFIRMARY.—At the meeting of the governors of the Gloucester Infirmary held on Dec. 31st, 1903, the chairman, Colonel Curtis Hayward, reported that of the £10,000 required for building the nurses' home and effecting improvements in the infirmary £7500 had been already received.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

LONDON HOSPITAL.

23 CONSECUTIVE CASES OF OPERATION UPON THE STOMACH.

(Under the care of Mr. C. W. MANSELL MOULLIN.)

THE following notes, for which we are indebted to Mr. C. H. Miller, are the record of 23 consecutive cases of operation upon the stomach during his term of office as house surgeon from March to November, 1903.

CASE 1.—The patient was a married woman, aged 27 years, who was admitted on March 26th. She had always enjoyed good health until 12 months before, when she began to suffer from pain in the epigastrium. It nearly always began two hours after food and was relieved by sickness. Four months before admission she vomited a large quantity of dark blood and this occurred again four weeks later. In spite of being strictly dieted and kept in bed the symptoms steadily grew worse and the patient kept losing ground. The abdomen was hollow. There was no dilatation of the stomach and there was no superficial hyperæsthesia, but there was one spot by the tip of the left tenth rib which was very tender on deep pressure. Laparotomy was performed on March 31st and the scar of an old ulcer was found on the serous coat near the pylorus. Posterior retrocolic gastro-jejunostomy was performed and a lateral anastomosis was made between the two sides of the jejunal loop, both by direct suture. The patient vomited three times in the course of the night. Small quantities of water were given by the mouth the same evening and pancreatised milk the next day. Nutrient enemata were administered for the first 24 hours and at the end of that time calomel in two grain doses every four hours up to ten grains was given. This was followed by a turpentine enema, after which the bowels acted well. The patient was given soft solids at the end of the week and left the hospital perfectly well on April 25th.

CASE 2.—The patient, a single woman, aged 28 years, was admitted on April 22nd. She gave a history of indigestion for the last ten years and of violent epigastric pain and vomiting, especially after solid food, for the last six months. The pain usually began half an hour after food and was relieved by vomiting. There was no history of hæmatemesis or of melæna. The abdomen was rigid, especially over the upper part of the right rectus. There was a point of superficial tenderness two inches above the umbilicus and one inch to the left of the middle line and of deep tenderness in the right epigastrium. When the abdomen was opened stenosis of the pylorus was found, due to the scar of an old ulcer, and posterior retrocolic gastro-jejunostomy with a lateral anastomosis was performed by direct suture as in Case 1. The after-treatment was the same. Pancreatised milk was given by the mouth after 24 hours and solid food at the end of a week. The patient was discharged well on May 25th.

CASE 3.—The patient, a man, aged 36 years, was admitted on April 23rd. He gave a history of pain in the epigastrium and vomiting for the last six years. Hæmatemesis occurred in 1900. In 1902 the abdomen was explored and a duodenal ulcer was found. This was scraped and painted with nitrate of silver but without giving the patient any relief. Vomiting continued three or four times a day. The abdomen was opened and a great mass of adhesions was found around the pylorus and the first part of the duodenum matting everything together. The same operation was performed as in the previous cases. Peptonised milk was given after 24 hours. The vomiting ceased and the patient made uninterrupted progress for three weeks, when the pain and vomiting returned for a time. He was discharged at the end of four and a half weeks and was seen again two months later in much better condition and free from all symptoms but an occasional attack of indigestion.

CASE 4.—The patient, a man, aged 44 years, was admitted on June 11th. He had suffered from indigestion as long as he could remember, the pain coming on half an hour after food. There had been two attacks of hæmatemesis in June, 1902. After this the patient was strictly dieted but without obtaining any relief. On examination the epigastrium was rigid; there was no deep tenderness but there was superficial tenderness at the back of both loins. When the abdomen was opened a number of adhesions were found on the posterior surface of the stomach around the pylorus. The same operation was performed and everything went well until the fifth day, when it was discovered that the wound in the abdominal wall (which had been sewn up with catgut boiled in xylol) had given way and that there was a large prolapse of intestine. This was replaced as soon as possible under an anæsthetic but the patient, in spite of being transfused twice, never rallied from the shock and died 36 hours later. At the post-mortem examination there was no peritonitis or leakage from the operation wounds nor was there any physical sign to account for his death.

CASE 5.—The patient, a woman, aged 33 years, was admitted on May 13th, being sent by Dr. F. J. Smith. A history of pain after food, with occasional vomiting for the last four years, was given, the symptoms steadily growing more severe. Three months before admission she had vomited half a pint of blood. On examination there were much tenderness in the epigastric and right hypochondriac regions and some superficial tenderness between the scapulæ. The abdominal muscles were contracted and the abdomen was very rigid. No scar was visible on the serous surface of the stomach. The same operation was performed. Sickness was almost continuous for four days. At the end of that time it ceased and the patient was able to take semi solid food at once. She was discharged to a convalescent home on the twenty-second day after the operation and reported herself on her return as feeling perfectly well and quite free from pain.

CASE 6.—The patient, a man, aged 37 years, was admitted on May 14th. He gave a history of pain coming on one hour after food for the last 12 months. The pain was usually relieved by vomiting but occasionally persisted for some hours with great intensity. There was no hæmatemesis or melæna. No superficial or deep tenderness was present and no tumour could be felt. On opening the abdomen the stomach was found to be dilated and there was much thickening with some adhesions around the pylorus. The same operation was performed and the patient was discharged well on June 17th. Two months later his condition was perfectly satisfactory.

CASE 7.—The patient, a woman, aged 50 years, was admitted on June 18th and gave a history of indigestion and vomiting for many years. As a rule vomiting relieved the pain. Seven weeks before admission she was reported to have brought up 12 pints of blood and to have suffered from melæna for some days. On examination the upper part of the abdomen was rigid and there were deep tenderness and pain in [illegible] There was no superficial tendern[illegible] felt. On opening the abdome[illegible] the stomach wall near the pylorus and some adhesions were found at the cardiac end. The stomach was opened and the interior was examined with a speculum to ascertain if there was any bleeding point. An anterior gastro-jejunostomy (making use of the opening through which the interior had been explored) with a lateral anastomosis between the contiguous sides of the jejunal loop was performed. This was followed by a good deal of bleeding, the patient continuing to vomit, first bright and then dark blood, until she became seriously anæmic. The bleeding stopped [illegible] after several drachm doses of [illegible] e vomiting continued with dim[illegible]; but in spite of this she was able to take and to retain small quantities of peptonised milk and iced champagne and on the fifth day was given semi-solid food. After this there was no further trouble and she was discharged on July 20th able to eat anything without inconvenience.

CASE 8.—The patient, a man, aged 54 years, was admitted on June 18th. He gave a history of pain and vomiting for upwards of eight years, which had been steadily getting worse. There was no history of hæmatemesis. He had lost three stones in weight in the last twelve months. On examination of the abdomen there was no superficial tenderness but the upper segment of the right rectus was rigid and here pressure caused a good deal of pain. The stomach was distended. There was a well-marked splashing sound but no tumour and no enlarged glands could be made out. On opening the abdomen the pylorus was surrounded by adhesions and on the anterior surface was an old scar. The whole of the lesser curvature was occupied by a mass which appeared to be carcinomatous. A posterior gastro-jejunostomy with a lateral anastomosis was performed. For the first 24 hours the patient was very sick but after that he took small quantities of pancreatised milk readily. Convalescence was protracted by a severe attack of bronchitis but the patient was discharged able to eat ordinary diet without pain or sickness on July 21st and when seen a month later had continued well and had gained in weight.

CASE 9.—The patient, a man, aged 25 years, was transferred to the surgical wards by Dr. Smith on June 22nd. There was a history of vomiting several times a day for the last seven weeks and of having brought up large quantities of blood on more than one occasion. There had been but little pain and that chiefly in the left loin (the patient had evidently had morphine freely). On opening the abdomen a cicatrix was at once visible on the anterior surface of the stomach near the cardiac end of the lesser curvature, and on opening the stomach through its anterior wall a deep crater-like ulcer was found in a position corresponding with that of the scar. An anterior gastro jejunostomy with a lateral anastomosis was performed by direct suture and as the patient was somewhat collapsed a pint of beef-tea with two ounces of brandy was injected by means of a catheter into the descending side of the loop. After the operation he was very restless and vomited frequently for the first 48 hours. As the pulse became very weak, continuous infusion of saline solution was performed on the third day, upwards of ten pints being injected. After this his condition improved rapidly. The vomiting ceased. Food was taken regularly and he was discharged from hospital on July 30th. Two months later he came back to report himself as quite strong and free from any unpleasant symptoms. He had put on more than a stone in weight.

CASE 10.—The patient, a woman, aged 23 years, was admitted on June 24th, being sent by Dr. Smith. She gave a history of hæmatemesis four years before, followed by pain and nausea after food. Four days before admission she had brought up a large quantity of blood and again on three occasions since. The motions had been black for some days. The abdomen was rather rigid but there was no superficial or deep tenderness and no tumour could be felt. After some days' feeding by enemata an operation was performed on July 7th and an old ulcer was found on the lesser curvature near the pyloric end. It could not be excised so a posterior gastro-jejunostomy was established with a lateral anastomosis as already described. The vomiting was severe for the first two days but ceased as soon as the bowels were well opened. The patient made an uninterrupted convalescence and was discharged to the country 25 days after the operation.

CASE 11.—The patient, a woman, aged 45 years, was admitted on July 4th, being sent in by Dr. A. P. Gibbons. A history of pain after food, relieved by vomiting, for many years past and of hæmatemesis and melæna two days before admission was given. The pain was chiefly in the right epigastric region, penetrating through to the back. There was no superficial or deep tenderness and no tumour or dilatation of the stomach could be made out. On opening the abdomen an old indurated chronic ulcer was found occupying the lesser curvature of the stomach. This was excised and as the shape of the stomach after the wound in its walls had been sewn up was not satisfactory a posterior gastro-jejunostomy without any lateral anastomosis was performed as well. The patient was seriously collapsed in spite of large saline enemata and was transfused (intravenous) to the amount of three and a half pints on the same [illegible] hypodermically [illegible] On the follow[illegible] [illegible]ll quantities of [illegible] food at the end [illegible] st 6th, free from pain, able to take food well, and gaining weight rapidly.

CASE 12.—The patient, a woman, aged 39 years, was transferred to the surgical wards by Dr. G Schorstein on July 13th. A history of pain after food for many years past was given which was relieved by vomiting. Lately the amount brought up had occasionally been excessive. On examination the stomach was much dilated; splashing could easily be obtained and there was an ill-defined induration in the lower part of the epigastric region. On opening the abdomen the transverse colon was found to be extensively adherent to the greater curvature and the pyloric end of the stomach was much contracted by scar tissue. The posterior operation was impossible so an anterior gastro jejunostomy with a lateral anastomosis was performed. The patient was transfused (intravenous) to the extent of three pints on the same evening. There was no vomiting and after 24 hours she took pancreatised milk well. She was discharged to a convalescent home on August 8th.

Case 13.—The patient, a woman, aged 30 years, was admitted on July 20th with a history of pain after food, which was relieved by vomiting, and of hæmatemesis and melæna on several occasions The abdomen had been already explored at another hospital but apparently nothing had been found and the stomach had not been opened. The patient was fed on nutrient enemata for 12 days before anything was done in the hope of improving her general condition. On opening the abdomen many adhesions were found around the transverse colon and the posterior surface of the stomach. The interior of the stomach was examined with a speculum, but no ulceration was seen and the opening made for this purpose was utilised for an anterior gastrojejunostomy. A lateral anastomosis was also made. On the same night the patient was transfused, three pints being injected into the veins, and nutrient enemata were given for 24 hours. The vomiting in this case was very persistent for four days and only ceased at the end of the week. 14 days later it began again and the loss of fluid was so great that subcutaneous transfusion to the amount of 12 pints was performed. The cause for this attack was never discovered. The temperature rose to 103° F. and remained irregular for about a fortnight and vomiting continued during the whole period once or twice a day, but it was noted that it made no difference to the patient's meals. An hour after food she would be sick without, however, bringing up anything that could be recognised as part of her last meal. Finally the vomiting ceased entirely on her going to a convalescent home and the condition of the patient improved very much.

Case 14.—The patient, a man, aged 30 years, was admitted on August 24th. There was a history of indigestion for years past, of frequent vomiting, and of one attack of hæmatemesis and melæna six days before admission. There was marked superficial tenderness on the whole of the upper part of the abdomen, with some deep tenderness in the right epigastric region. For some time the patient was dieted but as there was no improvement an operation was performed on Oct. 10th on Mr. Mansell Moullin's return. The pylorus was found to be thickened and contracted and to be fixed by adhesions to surrounding structures. As there was not a great amount of cicatricial tissue pyloroplasty was performed and a gauze drain (as there was a certain amount of oozing) was left for 48 hours. Vomiting was severe for three days and continued until the seventh Liquid food was given after 24 hours and convalescence after that was uninterrupted. The patient left the hospital completely relieved 25 days after the operation.

Case 15.—The patient, a woman, aged 50 years, was transferred to the surgical wards by Dr. Schorstein on Sept. 29th. A history of severe hæmatemesis on two occasions eight years before and of continuous pain after food since was given. Vomiting was frequent, the patient sometimes bringing up a pint or more of acid fluid. There was superficial tenderness over the whole of the upper part of the abdomen and over the lumbar spines. The stomach was evidently dilated and a cylindrical hard mass could be felt midway between the umbilicus and the ensiform cartilage. On opening the abdomen the lesser curvature of the stomach, especially towards the pyloric end, was found to be extensively infiltrated with old inflammatory deposits and the scar of an old ulcer was visible near the pylorus. Posterior gastro-jejunostomy with a lateral anastomosis was performed as described already. The patient vomited almost every hour for the first two days and then the vomiting ceased. At the end of a week she was taking soft solids without discomfort and she left the hospital in a month after the operation free from pain and feeling well.

Case 16.—The patient, a woman, aged 30 years, was admitted on Oct. 3rd with a history of indigestion with occasional hæmatemesis five years ago and of vomiting at intervals ever since, to the amount at times of many pints. Nausea after food was the rule but sickness was only occasional. Sometimes there was severe pain but this did not bear any relation to meals. The stomach was considerably dilated but no splashing could be made out. On opening the abdomen the pylorus was found to be constricted by the scar of an old ulcer and pyloroplasty was performed. This patient suffered from a good deal of flatulence at first and though when she was discharged on Oct. 31st this had disappeared there was an occasional feeling of nausea. It seemed as if the stomach, the walls of which were more or less atonic, did not empty itself so well through the enlarged pylorus as it usually does through a low gastro-jejunostomy.

Case 17.—The patient, a woman, aged 47 years, was admitted on Oct. 10th. There was a history of epigastric pain commencing the previous Christmas and followed after some time by vomiting. The pain was continuous and not relieved by sickness. The amount brought up was very small and appeared to consist chiefly of bile. The patient was very much wasted (her weight having fallen from 13 to 7½ stones) and she was deeply under morphine on admission. On examining the abdomen the upper segments of the rectus were rigid; there were both superficial and deep tenderness in the epigastrium and the stomach resonance was increased. On opening the abdomen no examination of the viscera was made owing to the patient's condition but a posterior gastro enterostomy with a lateral anastomosis was performed as quickly as possible. Hot saline fluid and brandy were injected into the small intestine during the operation and a large enema was given immediately after. On returning to the ward she was transfused to the amount of five pints. The operation had no effect upon the vomiting which continued as before. Food was rarely brought up. As a rule the ejecta consisted chiefly of bile with watery fluid as they had before the operation. On two occasions, at some days' interval, the patient became so collapsed that continuous transfusion was necessary. Towards the end she grew maniacal, so that it was very difficult to restrain her, and she died 24 days after the operation. At the post-mortem examination there was no peritonitis and both openings were perfect and apparently able to do their work well. There was no disease of the stomach, the liver, or the intestines. Unfortunately the head was not opened.

Case 18.—The patient, a man, aged 32 years, was admitted on Oct. 12th. In March, while stooping to put on his boots, he was seized with severe pain in the pit of the stomach and fainted. Later a large amount of blood was passed per rectum. Since then he had had two similar attacks. He had never been sick but had suffered since the first attack from epigastric pain which came on ten minutes after taking food and lasted for hours. There was no superficial or deep tenderness over the abdomen and no tumour could be felt but the stomach appeared to be a little dilated. On opening the abdomen there did not appear to be anything the matter with the stomach. A posterior gastrojejunostomy with a lateral anastomosis was performed in the usual way. The patient was sick three times and convalesced rapidly, leaving the hospital at the end of a month able to take food well and perfectly free from pain. In this case it is probable that the ulcer was in the duodenum.

Case 19.—The patient, a man, aged 36 years, was admitted on Oct. 19th, being sent in by Dr. Robert Hutchison. A history of abdominal pain for the last six months coming on after food and relieved by vomiting was given. He had never had hæmatemesis. The amount brought up was often very large. The stomach was very much enlarged and splashing was easily obtained. On opening the abdomen a hard fibrous ring was found surrounding the pylorus. Posterior gastro-jejunostomy with a lateral anastomosis was performed. There was no vomiting and the patient was discharged well and free from symptoms on Nov. 12th.

Case 20.—The patient, a woman, aged 23 years, was admitted on Oct. 30th. Six years before she had been in another hospital with symptoms of gastric ulcer. She had had no symptoms for three years after. For the last two years the pain after food had been growing more and more severe and for the last few months there had been incessant vomiting. There was well-marked superficial tenderness over the area corresponding to the eighth and ninth right dorsal nerves and there was deep tenderness in the epigastrium. On opening the abdomen there was a hard puckered scar on the lesser curvature, with a portion of the great omentum firmly adherent to it and stretched like a strap across the front of the stomach. Posterior gastrojejunostomy with a lateral anastomosis was performed. The patient was sick nine times in the first two days and suffered from a severe attack of bronchitis This delayed convalescence somewhat but she left the hospital on Nov 28th free from pain and taking food well

CASE 21 —The patient, a man, aged 36 years, was admitted on Nov 3rd with a history of pain with occasional sickness for the last nine years, which had been growing worse of late He had never had hæmatemesis but occasionally had brought up enormous quantities of fluid The lower border of the stomach could be felt below the umbilicus and there was distinct splashing On opening the abdomen the lesser curvature was obliterated by scar tissue which had dragged the pylorus quite close to the cardia It was difficult to say if the thickening was due to malignant disease or not. A posterior gastro jejunostomy with lateral anastomosis was performed The patient vomited four times in the first 24 hours and three times in the second Further progress was uneventful and he was discharged to a convalescent home on Dec 7th in a much improved condition

CASE 22 —The patient, a man, aged 43 years, was transferred to the surgical wards by Dr Hutchison on Nov 6th A history of having vomited two quarts of blood 20 months before and of having vomited one pint and suffered from melæna one month before was given He had suffered severely from pain after food and had found relief by making himself sick He had lost over two stones in weight recently On examination the stomach resonance was increased, a distinct splash was heard, there was no superficial tenderness but the upper part of the right rectus was rigid. The patient was very flabby and had suffered from chronic pleurisy On opening the abdomen a large hard mass was found at the cardiac end of the lesser curvature and there were many enlarged glands It was difficult to say whether it was malignant or not A posterior gastro jejunostomy with a lateral anastomosis was performed in the usual way The patient convalesced rapidly and was discharged on Dec 3rd He still suffered from attacks of pain which, however, were relieved by food and by hot drinks There was no nausea or vomiting

CASE 23 —The patient, a woman, aged 36 years was transferred to the surgical wards by Dr F J Smith on Nov 9th There was a history of pain after food with occasional vomiting for 15 years The symptoms had been growing more severe There was no hæmatemesis but probably some melæna. For some time past she had lived mainly on peptonised milk On examination the upper part of the abdomen was very rigid, especially on the left side Deep palpation was impossible owing to the extreme tenderness On opening the abdomen the stomach was found to be shaped like an hour glass, partly from the effects of an old ulcer on the lesser curvature and partly from the constriction caused by a band of omentum which was adherent to the scar As the stomach could not be drawn out of the abdominal wound an anterior gastro jejunostomy with a lateral anastomosis was performed in the usual way The patient was sick nine times altogether in the course of the first three days For some days after beginning to take solid food she complained of occasional slight pain but this entirely ceased after Nov 23rd and she was discharged to a convalescent home greatly improved in condition on Dec 5th

Remarks by Mr MANSELL MOULLIN —Of the 23 cases gastro jejunostomy was performed in 20, pyloroplasty in two, and excision of the ulcer with gastro jejunostomy in one The ideal operation for gastric ulcer is undoubtedly excision but it can rarely be performed either because the ulcer or the scar is too near to the pylorus or because the ulcer has attained such a size, from having been left too long, that such a proceeding would interfere with the shape of the stomach In two of the cases the ulcer was in the duodenum, where excision can rarely be carried out

The operation which I adopted in nearly all the cases was a posterior retrocolic gastro jejunostomy with, in addition, a lateral anastomosis between the adjacent sides of the jejunal loop, and the union was in all cases carried out by direct suture with silk and an ordinary needle The lateral anastomosis may prolong the operation a few minutes, certainly not more than ten, but on the other hand, it enables the patient to be fed at once in the best possible way, by introducing food directly into the bowel (and in many of these cases this is of the greatest service), it effectually prevents the possibility of such a thing as a vicious circle, and it renders the portion of the bowel which descends from the stomach through the opening in the mesocolon sufficiently rigid to check the rest of the small intestine from passing through the opening into the lesser peritoneal cavity, an accident which is said to have occurred on several occasions

In every case the patients were given immediately before the operation one thirtieth of a grain of strychnine with either one hundredth of a grain of digitalin or two grains of sodio salicylate of caffeine hypodermically, and an enema of 18 ounces of black coffee with two ounces of brandy In several the injection of strychnine and caffeine was repeated as soon as the operation was over, and in a few, owing to the state of the pulse, the same injection was given at six hours' intervals for several days A second enema of a pint either of saline fluid or of beef tea (it seemed to make little or no difference) with some more brandy was given as soon as the patient was back in bed, and nutrient injections of at least 12 ounces each were given at four hour intervals for 24 hours The patients were allowed small sips of water the same evening Small quantities of peptonised milk were given by the mouth after 24 hours and by the fourth day nearly all could take soft solids without inconvenience Morphine was always given the first night to relieve the pain and to secure a good night's rest, but not afterwards Two grains of calomel were given at the end of 24 hours and repeated every four hours up to ten grains Then a copious enema with an ounce of turpentine usually caused the bowels to act freely The most troublesome feature was the vomiting A small minority did not vomit at all Most of the patients were sick for 48 or 72 hour, regardless of what was done for them. In many instances they were able to take fair quantities of milk in the intervals between the acts of sickness and to retain it Even when food had been taken only a few minutes before the ejecta consisted chiefly of an acid brownish fluid Shock was met by injections of strychnine and caffeine, by raising the foot of the bed and bandaging the limbs, and in severe cases by intravenous transfusion Subcutaneous transfusion was employed with great benefit in those cases in which the loss of fluid by vomiting was excessive The fluid used was simple saline solution I have tried the addition of grape sugar but it seemed to cause more pain and I was not able to find that it possessed any compensatory advantage Two patients died one from shock following prolapse of the bowel owing to the wound in the abdominal wall giving way on the fifth day (I have not trusted to catgut boiled in xylol since), and the other at the end of three weeks from persistence of the symptoms for which the operation had been performed It did not give any relief In both the artificial communication was sound, without a sign of leakage, and appeared to be capable of doing all that was required of it

With regard to the state of the patients at the time of discharge nearly all were completely relieved of their symptoms Those in whom the stomach was much dilated and atonied still had dyspepsia at times and one or two in whom there were extensive perigastric or periduodenal adhesions continued to suffer a certain amount of pain Neither excision of the ulcer nor gastro jejunostomy can prevent that in such cases Both operations work wonders but neither one nor the other, nor both together, can give absolution from the consequences of ulceration which has been allowed to progress unchecked *for years Operation to be a success,* must be performed while the condition is still curable

---

GOVERNMENT CIVIL HOSPITAL, HONG-KONG

A CASE OF DOUBLE AMPUTATION, RECOVERY

(Under the care of Mr E A R LAING, assistant superintendent)

A CHINESE male, aged 29 years, was admitted into hospital suffering from injuries by dynamite Both arms were blown off and both eyes were completely destroyed The accident had occurred 36 hours previously and the undressed wounds were in a filthy condition Chloroform was administered by Dr W V M Koch and both arms were at once amputated simultaneously above the elbow, the left by Mr J Bell, superintendent, and the right by Mr Laing The patient stood the operation well, only requiring one hypodermic injection of *strychnine The after treatment was uneventful* though there was a good deal of fever due to the condition of the face and eyes and he was discharged six weeks after, of course totally blind.

Remarks by Mr. LAING.—Double amputations not being very common it was thought worth while putting this case on record. The patient was young and a fisherman and had got over the primary shock, so everything was in his favour save the very septic condition of the wounds.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Staphylococcus Aureus and Rheumatic Fever.—Dermoid Tumours of the Brain.—Racemose Aneurysm of the Brain.—Pulsating Exophthalmos with Aneurysms of the Internal Carotid.—Epithelioma of the Cervix treated by Passive Immunisation Therapy of Dr. Otto Schmidt.

A MEETING of this society was held on Jan. 5th, Mr. R. J. GODLEE, the President, being in the chair.

Dr. F. J. POYNTON and Dr. W. V. SHAW brought forward a paper in continuation of recent investigations upon the Pathogenesis of Rheumatic Fever and in support of the specific nature of the disease. Their observations were founded upon clinical, pathological, bacteriological, and experimental observation and they dwelt upon the importance of this broad survey of facts in studying rheumatic fever for the avoidance of side issues. Many people spoke of rheumatic fever in a vague way as an attenuated pyæmia and the result of any infection which might cause pyæmia. Dr. Poynton and Dr. Shaw were opposed to this contention, holding that rheumatic fever had a definite clinical entity, as much, for example, as tuberculosis. They relied entirely on fatal cases for their arguments. Supposing rheumatic fever were merely an attenuated pyæmia then they believed that the staphylococcus aureus, one of the most important causes of pyæmia in man, should also be a frequent cause of rheumatic fever. This, however, did not prove to be the case. The research was then described. Firstly, it was demonstrated that the two micro organisms, the staphylococcus aureus and the diplococcus rheumaticus, could be easily distinguished from one another; secondly, in 25 fatal cases of rheumatic fever investigated by Dr. A. Paine and themselves they had not found the staphylococcus aureus on culture or in the lesions; thirdly, in cases from which they had isolated the staphylococcus aureus from human tissues the condition had not been rheumatic fever; and, fourthly, they had studied the experimental results produced by injecting pure cultures of the staphylococcus aureus into rabbits and pure cultures of the diplococcus rheumaticus into rabbits and monkeys, this latter investigation with monkeys having been already published by Dr. Shaw.[1] These micro-organisms had been attenuated and treated under similar conditions. The staphylococcus produced septicæmia or pyæmia with multiple abscesses, or no result. The diplococcus produced the manifestations of rheumatic fever or no result. They criticised the attitude of mind which demanded constant results of a regulation disease in animals in response to an infection; it did not occur in man, nor was it to be expected in animals, for the symptoms varied with the virulence of the infection and the resistance of the tissues. Lastly, they had studied the effect of mixed infections with these two micro-organisms. Rabbits and monkeys had been used. In some cases both micro-organisms were injected simultaneously; in others the diplococcus was injected first and after recovery the staphylococcus aureus. The results were these. When the injections were simultaneous death was rapid and pyæmic abscesses containing the staphylococcus were found and also arthritis and in some cases endocarditis. The staphylococcus was most easily found in the blood and the diplococcus in the joints. Both micro-organisms were demonstrated in the tissues and isolated after death. When the staphylococcic infection followed the rheumatic the disease that developed was a pyæmia or rapidly fatal septicæmia. So far as it was admissible to argue from these experiments to clinical medicine the staphylococcus aureus, far from producing in mixed infection rheumatic fever, produced a pyæmia with multiple abscesses or a rapid septicæmia. A study of a clinical case of mixed infection by Dr. Paine and Dr. Poynton was described. The patient, a boy who was suffering from cellulitis of a leg, developed arthritis and pericarditis. In spite of the cellulitis the symptoms were so very similar to rheumatic fever as to raise this point in diagnosis. After death purulent pericarditis, arthritis, and multiple abscesses were found and Dr. Paine isolated from the pus the staphylococcus aureus and a diplococcus. The final conclusions were: (1) the staphylococcus aureus was not a cause of rheumatic fever either in simple or mixed infection; and (2) rheumatic fever was not an attenuated pyæmia so far as the staphylococcus aureus was concerned. The paper was illustrated by macroscopic and microscopic preparations, drawings, lantern slides, and cultures.

Dr. H. M. STEWART showed a specimen of Dermoid Tumours situated at the Base of the Brain. There were two tumours; one was of the size of a hazel-nut in the situation of the pituitary body, which showed the structure of a dermoid cyst; and the other, a large tumour, was situated between the frontal lobes and consisted of the wax-like material frequently found in dermoid cysts but with no epithelial elements. The patient was a man, aged 31 years, who had had syphilis five years previously and had suffered from headache for nine months. There were no other symptoms until a few days before death when he became feverish and vomited. The condition temporarily improved, then vomiting returned, and the patient died suddenly.

Dr. E. F. BUZZARD showed a specimen of Dermoid Tumour in the Brain. The patient, a boy, aged 14 years, complained of having had fits and paroxysmal attacks of headache and vomiting during the previous 12 months and on examination he proved to have very intense optic neuritis but no definite localising signs of his intracranial lesion. The boy died and at the necropsy a large dermoid tumour was found on the orbital surface of the frontal lobes. This tumour lay between the dura mater and lepto meninges and was non-adherent to the former but firmly attached to the latter in the region of the right Sylvian fissure. It had invaginated the brain tissue in this part and extended across the mid-line to the corresponding portion of the left hemisphere where it was not so deeply imbedded. The wall of the tumour was only definite on the right side and proved on microscopical examination to consist of definite skin tissue containing sebaceous glands and hair follicles. Outside this the pia arachnoid was much thickened and in places calcareous. The tumour itself was composed of greasy, crumbly, sebaceous material in which could be distinguished numerous hairs, epithelial débris, and fatty globules of varying size. The appearances suggested that the dermoid growth originated on the right side of the brain where the wall was best marked and that about the age of puberty the sebaceous glands took on great secreting activity with the result that the material so formed was gradually forced across the mid-line in front of the optic chiasma until it occupied the area seen at the necropsy. Apart from their great rarity, considerable interest attached to the presence of dermoid tumours in the brain owing to the obscurity of the source from which they spring and to the relation, if any, they bear to the less rare cholesteatomata. More recent writers, and in particular Bostroem, who had given very great attention to the subject, believed that every gradation could be found between a pial dermoid and a cholesteatoma and that both were epithelial in origin, thus opposing the older view which favoured the endothelial character of the latter.

Dr. J. H. DRYSDALE showed a case of Racemose Aneurysm of the Brain. The specimen was removed from a woman, aged 26 years, who had suffered from epileptic fits for 11 years. Ten days before death she had a fit and passed into a state of unconsciousness with weakness and rigidity of the left side. The coma deepened and the patient died. At the necropsy, on the right side of the brain a large area of greatly enlarged tortuous vessels filled with blood obscured the surface of the brain, filling the sulci and covering the intervening convolutions. The area extended forwards from the Rolandic fissure and was limited, though not quite strictly, to the convex surface of the brain. The right middle cerebral artery shortly after entering the Sylvian fissure was greatly and irregularly dilated, more especially as to its anterior branch which fed the large mass of vessels, one of which was almost as large as an ordinary brachial artery. Towards the anterior and inner portion there entered one of the anastomosing branches of the anterior cerebral vessel dilated to a size larger than that of an ordinary radial artery. A small quantity of effused blood was found at the base of the brain but this did not extend to the convexity. A vertical transverse section of the hemisphere showed a wedge-shaped mass of vessels extending down into the substance of the white matter and looking on section almost like a cavernous angeioma. On microscopical examination the main mass was seen to consist of spaces of varying sizes filled with blood. The walls of the spaces varied considerably in thickness. The condition corresponded to what was known in England as a cirsoid aneurysm.

---

[1] Journal of Pathology and Bacteriology, December, 1903.

Mr. **HAROLD L. BARNARD** read the notes of a case of Traumatic Pulsating Exophthalmos consequent upon a bullet wound in the base of the skull. The patient, a male, aged 40 years, had shot himself in the mouth with a pistol. On admission to hospital he was conscious; there was left external ophthalmoplegia with loss of vision, pulsating exophthalmos, left facial paralysis, and discharge of blood and cerebro spinal fluid from the left external auditory meatus. Compression of the carotid artery caused cessation of pulsation and diminution in proptosis. Mr. Barnard performed ligature of the left common carotid artery on the day of admission into hospital. The artery was ligatured in two places and divided between. For some reason the ligature slipped off the proximal cut end, giving rise to alarming hæmorrhage. Mr. Barnard described how he had reapplied the ligature, although some difficulty was experienced in finding the end of the vessel which had retracted into its sheath The pulsation and swelling of the left eye subsided immediately upon applying the ligature but recurred slightly after a few days and then finally ceased in ten days; paralysis and blindness, however, persisted. Two months after this operation the patient developed signs of cerebral irritation; skiagrams were taken and the bullet was located in the middle fossa. A trephine opening was made in the squamous part of the left temporal bone and the bullet was found lying in the middle fossa surrounded by pus and portions of the shattered tegmen tympani; these were removed and a drain was inserted. The patient, however, developed a hernia cerebri and died two and a half months after admission into the hospital. At the post mortem examination an abscess was found in the left temporo sphenoidal lobe unopened and independent of the collection of pus in the middle fossa which had been efficiently drained.—Mr. **HUGH M. RIGBY** then described a Dissection of the Base of the Skull which had been removed at the post-mortem examination; the path taken by the bullet was shown and the condition of the internal carotid artery in its entire intracranial course. Two sacculated aneurysms were found, one at the first bend of the carotid in the petrous portion of the temporal bone and another at the second bend at the posterior end of the cavernous sinus. No arterio-venous communication was found and a noticeable feature was the absence of venous engorgement in either ophthalmic veins or cavernous sinus. Mr. Rigby laid emphasis on the fact that in this case the signs and symptoms of pulsating exophthalmos were due, not to an arterio-venous communication, as is said to be usually the case, but to the presence of an aneurysm. A reference to the best known papers on this subject showed what a difference of opinion existed on this point. The question of the treatment of this condition by ligature *of the common carotid artery* was next discussed and defended both by the results of statistics and the result in the present case, both aneurysmal sacs having been found completely filled by firm clot.

Dr. **R. N. SALAMAN** exhibited the Pelvic Organs of a case of Epithelioma of the Cervix from a patient who had been treated by the so called passive immunisation therapy of Dr. Otto Schmidt of Cologne, and whose case was referred to in the address given by Dr. H. Jossé Johnson to the Abernethian Society on Nov. 5th, 1903.[1] In this latter address attention was drawn to the occurrence of intestinal obstruction during the course of the treatment, and this together with the uræmic symptoms which ushered in death were ascribed to an undue fibrous formation, and "inconvenient cicatrisation" or overcure on the part of the diseased tissues under the curative stimulus of the serum. Microscopical preparations, both from the stricture of the colon and from the infiltrated anterior vaginal wall at the point where the ureter was constricted, showed clearly that not only was there no undue fibrosis but that the constricting agent in each case had been actively proliferating epitheliomatous deposits which were replacing the fibrous and muscular walls of both gut and ureter. The sections demonstrated also the absence of any evidence suggestive of atrophic growth, nor were there any more marked retrogressive cellular changes than could be observed in any case of epithelioma. The section of the gland from the left iliac region showed an active inflammation as well as the hyperplasia of endothelium found in cases of chronic irritation. *The following were the outlines of the treatment and clinical* course of the illness as very kindly supplied by Dr. Kochmann, in whose charge the case was. Oct. 22nd, 1901: Abdominal hysterectomy for fibroids; the right ovary was also removed (the cervix, since examined, was epitheliomatous). December, 1901, to January, 1902: Recurrent vaginal hæmorrhages. Feb 12th, 1902: Curettage of new growth in the vagina. End of April, 1902: Laparotomy performed in Berlin with view to radical operation. This was abandoned and the vaginal growth was curetted and cauterised with chloride of zinc. Sept. 3rd, 1902: Further cauterisation. April 6th, 1903: Dr. Otto Schmidt injected his serum, which was repeated twice at weekly intervals. No reaction apart from pain and swelling in immediate neighbourhood of the injection was observed. End of April, 1903: For ten weeks treated by injections under the personal care of Dr. Schmidt in Cologne. July and August: Treatment by serum continued in London. August: Colotomy performed to relieve the intestinal obstruction. Serum treatment interrupted. Oct. 15th and onwards: Vomiting and uræmic symptoms. Nov. 7th; Death.

Reviews and Notices of Books.

Traité d'Hygiène. Procédés Rapides de Recherche des Falsifications et Altérations. (*A Treatise on Hygiene. Rapid Methods of Analysis for the Detection of Adulterations.*) Par le Dr. P. SMOLENSKY (de Saint-Pétersbourg). Traduction de russe par S. BROIDO et A. ZAGUELMANN. Annotées par L. GUIRAUD, Professeur d'Hygiène à la Faculté de Médecine de Toulouse, et A. GAUTIÉ, Préparateur du Cours d'Hygiène à la Faculté de Médecine de Toulouse. Paris: G. Steinheil, éditeur. 1904. Pp. xxxii.-752. Price 20 francs.

THIS book is a French edition of a work published contemporaneously in St. Petersburg by its Russian author and must, in fact, except in so far as the translation is concerned, be considered his work. There are, it is true, some footnotes written by the editors but these are few in number. Dr. Smolensky in his preface truly remarks that every man must eat and drink and must also be affected by his surroundings and that on that account what he eats, what he drinks, and the nature of his environment are all points of importance. He proceeds to state that in order to form a just opinion as to the good or bad qualities of these material objects which concern him so closely it is neither possible nor necessary to make a detailed examination in every case. What is practically necessary is, for example, to determine whether food is good or *bad, genuine or* adulterated, and to do so as quickly as possible. In such a case minute analyses, which necessitate a *well-fitted* laboratory, and the time necessary for carrying out the experiments may both be wanting and in the ordinary course of events in hospitals, asylums, and such places what is required is that the person responsible for the quality of the food should come to some immediate and correct decision in regard to the articles which are to be given to those under his care. The design of the book is to teach the best method by which such simple analyses are carried out—examinations which demand neither the use of costly chemical balances nor of high powers of the microscope. The author adds that almost all the necessary experiments described in the book can be carried out by means of apparatus to be found at the nearest shop devoted to chemical appliances. The aim and scope of the work are highly commendable and the reader may begin the highest expectations and the hope the very work for which he for years. A study of the volume itself may damp his ardour or may at least convince him that he will be unable to obtain some of the apparatus described without considerable delay. Dr. Smolensky wrote at St. Petersburg, the capital of a great country, and may be able to get Fesca's hydrostatic balance or Thörner's hydrometer at the shortest notice. The superintendent of, say, an English county lunatic asylum might indeed consider himself lucky if he could get and use such instruments whilst the patients waited for their dinner. It is at least doubtful if they would share his enthusiasm. Briefly, then, it must be confessed that the body of the book, considered from the point of view of a medical officer to a provincial asylum or "home," does not quite carry out the promise of the preface.

---

[1] THE LANCET, Nov. 14th, 1903, p. 1374.

Considered purely on its intrinsic merits the work possesses great value and it contains an enormous mass of useful information which is not to be found in any English text-book with which we are acquainted. We must confine our remarks to a brief outline of its contents. The first 13 chapters deal with food and in these the English reader will probably find something which is new to him on the subject of horseflesh, sour cream (which is a necessary adjunct to one of the best of Russian soups), eggs, and various grains which are not used as human food in Russia. There is also an instructive disquisition on sausages. Chapters XIV. to XVII. are devoted to alcoholic beverages, including kwass, a drink which is much affected by Russian peasants but which does not usually commend itself to the English palate. The chemical composition of this beverage is given, there is a recipe for its manufacture, and the researches of Ilinsky, Stéfanovitch, Téréchtchenko, and others on various points of interest which it presents are duly set forth. Separate chapters are devoted to tea, coffee, cocoa, condiments, vinegar, to the noxious colouring matters used in food and in other ways, and, finally, to the ills which may arise from cooking utensils. The portion of the book which treats of food occupies the chief part of the volume (pp. 1–531) and the remaining part is taken up by chapters on air, water, soil, housing, lighting, and clothing (pp. 532–687). Amongst the appendices are a long bibliographical index and a table of authors quoted in the text.

The work has distinct merits as a book of reference in dietetic questions pertaining to Russia but it should be clearly understood that it is by no means a waistcoat-pocket guide to show the busy man how to determine the purity of any given article of diet at five minutes' notice. The French edition is well printed on good paper and the illustrations are clear and readily comprehensible.

Encyclopædia Medica. Vol. XIII: Ulceration to Zinc Poisoning. Edinburgh: William Green and Sons. 1903. Pp. 584.

THE volume under review contains a few really good articles; the majority of the contributions are, however, of so condensed a character that the most which can be said for them is that they are fairly complete *résumés* of the subjects which they treat. As a reference to the list of authors will show, most of the articles have been written by experts. Nobody, however, finds more difficulty in condensing his knowledge on a specific subject than the man who knows most about it. Taken as a whole the general level of excellence hitherto attained in the previous volumes of this medical encyclopædia has been maintained in the present volume. Among the articles which call for special mention must be included that on the subject of Pathological Changes in Urine, by Dr. A. E. Garrod; perhaps we should not be far wrong in saying that this is among the best of the contributions to this volume. On the other hand, the article on Uric Acid is somewhat disappointing. The author, Dr. J. A Milroy, has clearly been embarrassed in his task by the very weight of his knowledge on this subject. Dr. T. B. Hyslop has apparently laboured under the same difficulty, for his disquisition on "Unconsciousness" is altogether too abstruse for ordinary readers who are not psychologists or alienists. Of its literary and scientific merits it is impossible to take two views but we think the article is out of place in the Encyclopædia Medica. Mrs E. Garrett Anderson and Mrs. M. A. D. Scharlieb represent the lady contributors to this volume, the former supplying an article on Vaccination and the latter an account of the Non malignant Tumours of the Uterus. The first of these two articles may be relied upon as an accurate record of the most important statistics on the subject and as a temperate and convincing exposition of the arguments for vaccination, and what is more important for revaccination. The gynæcological subjects included under the headings of uterus and vagina, especially from the point of view of treatment, are satisfactorily dealt with. Developmental Errors of the Uterus are described by Mr. A. E Giles and Malignant Tumours by Mr. J. Bland-Sutton The article on Vessels, by Dr. W. Russell, calls for special commendation. We think that the distinctions drawn by this author between atheroma and arterio-sclerosis would, if generally recognised and admitted, remove much of the ambiguity which obscures the correct understanding of the pathological processes involved in their production. The article on Visceral Pain by Dr. James Mackenzie has practical bearings and represents some excellent original work; the clinical methods of investigating the deep seated cources of abdominal pain are described and their degrees of trustworthiness are defined. In the appendix an omission in a previous volume is made good by an excellent account of Plague, and in conclusion we may remark that in our perusal of this volume we have discovered no gross error of fact or printer's lapse, with the exception of one instance of misspelling on p. 101, where "heating" is twice spelt "healing." This evidence of careful editorship reflects great credit on the individual contributors as well as upon Dr. D. Chalmers Watson, the editor in chief.

Notes on Alcohol. By Sir WALTER GILBEY, Bart. London: Vinton and Co. 1903. Pp. 31. Price 6*d*.

IT would be absurd to say that brandy, whisky, gin, and rum have the same physiological effect because they all contain alcohol. To the person *in extremis* genuine brandy is generally administered because it is known to be a more powerful restorative than any other spirit. Further, as Sir Walter Gilbey points out in the interesting brochure before us, the flavours of the various spirits are of importance, and according to his view, which we share, any deficiency as regards flavours renders the spirits less suitable for consumption. This amounts to saying that spirits are only satisfactory when they have been well matured, for as a rule raw or fresh spirit is objectionable to the palate, but in course of time these flavours which are at the initial stage unpleasant and probably also injurious are resolved into agreeable flavours of a harmless kind. There can be no doubt that by far the greater proportion of whisky upon the market consists, if not entirely of grain alcohol, of a mixture of that spirit and malt. Grain spirit is featureless and neutral as regard-taste; it is "silent," while malt spirit possesses a peculiar flavour and bouquet. Age effects no appreciable change in grain spirit at all commensurate with the effect of age upon a malt spirit. In a word, the fact of a malt spirit being drinkable is a guarantee of age, but the same does not apply to a grain spirit. Sir Walter Gilbey gives a very interesting history of the manufacture of spirit and his "Notes" contain some charming woodcuts illustrating distillation as it was in vogue two and a half centuries ago The woodcut facing the title page shows the interior of an early distillery and was published by John Taylor at "The Ship" in St. Paul's Churchyard in 1692. The woodcut on p. 3 shows the early pot-still and upon it is printed a recipe "how to make aqua vitæ out of beer." The spirit so obtained would be practically identical with modern whisky. This interesting drawing, it may be noted, was taken from a work entitled "*The Art of Distillation*," by *John French*, a doctor of physic, and was printed in 1561. Sir Walter Gilbey then gives an instructive account of the peculiarities of spirits obtained from different materials and by different methods. The appendix is devoted to the description of the patent still "invented by Mr. Æneas Coffey of the Dock Distillery, Dublin, distiller, fifth day of August in the first year of the reign of His Majesty King William IV., 1831." As is well known this system of producing alcohol is the most economical and accordingly patent spirit or grain spirit is especially used for blending with malt spirit which cannot obviously be produced so economically in the pot-still. If only the physiological effects of alcohol are desired grain spirit answers the purpose admirably. But there is very good reason for believing that spirit containing the peculiar products of the distillation of malt, wine, or sugar duly matured is not only more acceptable to the palate but less prejudicial to the health of the consumer. Sir Walter Gilbey goes a step further when he says that "it may be worth notice that a pure malt whisky certainly promotes temperance to a degree greater than a whisky deficient in flavour can do, for the neutral tasteless spirit added by the blender to new crude whisky diminishes its coarseness and by thus disguising the potency of the spirit gives a false impression as to its age. Again, the absence of flavour induces the consumer to mix much less water with his spirit than he would if he drank a well-matured pure malt whisky." There is a deal of truth in this. Those who wish to be familiar with the modern methods of producing spirit and of the art of blending will find all the necessary information in this instructive pamphlet. The public would appear to know very little of the question as to what is an all-malt spirit, an all grape spirit, or a blended spirit, but the publication of this little work leaves no excuse for such ignorance which, as long as it exists, is calculated to be prejudicial to the consumer's interests. We maintain that the consumer should be made aware of the character of the article which he is purchasing and that it should be insisted that upon the bottles of all spirits there should be printed a clear statement accurately describing the nature of the contents.

LIBRARY TABLE.

Consider the Children. By HONNOR MORTEN. London: R. Brimley Johnson. 1904. Pp. 80. Price 1*s.* net.—This is in many ways a very sensible book. Miss Morten considers, and we quite agree with her, that there is no useful purpose served in trying to teach children who are starving and that to teach infants—i.e., children under five years of age—for five hours per diem, three of which are consecutive, is ridiculous. She also considers that the subjects taught in board schools are far too numerous, a point which we have raised over and over again. We believe that we are correct when we state that the syllabus of the London School Board contains 36 different subjects. We do not altogether agree that corporal punishment should be done away with. Corporal punishment, provided that it is administered with a birch and then only by a head teacher, and is not carried out until some little time after the commission of the offence, is an excellent method of enforcing discipline. As for the food question, the difficulties in the way of supplying school children with food are notorious. The primary responsibility for feeding children rests with the parents who have brought them into the world and anything that lessens parental responsibility is a bad thing, but, on the other hand, it is useless to try to cram knowledge into children who are badly housed and insufficiently fed. Modern "educationists" seem to have entirely forgotten the meaning of the word "*educo*." Education should properly be a developing of intellect. Plants grow from seeds which are tended and nourished; the horticulturist does not take a full grown plant, cut it up into little bits, and ram it into the seed, as information is forced into the modern child. The type of education should be that employed by Socrates as given in the dialogue of "Meno." Miss Morten concludes with a chapter upon the religious wrangle. She is of opinion that the teaching in public elementary schools should be wholly secular. Into this question we shall not enter, for it is not our province to do so. But Miss Morten shows ignorance when (pp 77 and 79) she says that the State supports a body of clergy and buildings for the teaching of the State religion. That so clever a woman as Miss Morten should argue in this fashion is astounding when we look at her sensible remarks upon teaching and medical matters in schools in other parts of her book. The State no more pays for the clergy of the English Church than it does for the Salvation Army or for Miss Morten's last new hat The only clergy of the English Church paid by the State are some prison chaplains and the naval and military chaplains and these are paid in the same way as Roman Catholic and Presbyterian chaplains.

Leonora By ARNOLD BENNETT. London: Chatto and Windus. 1903 Pp. 362. Price 6*s.*—This novel is a very clever study of middle class life in the Potteries and Leonora, the protagonist, is a remarkable sketch of a woman who "found herself" when middle aged. Mr. Bennett's views upon medical men are somewhat peculiar. John Stanway, to avoid approaching ruin, took a large dose of morphine hypodermically. The medical man tried various remedies without success and went away. He returned after a while and went away again and then we are informed that "the doctor had said that he might survive many hours." No medical man would leave a case of morphine poisoning in this casual manner. But apart from this slip the book is excellent.

Natural Physical Remedies. By H. H. HULBERT, M.R C S Eng, L R C.P. Lond. London. Simpkin, Marshall, Hamilton, Kent, and Co., Limited 1903. Pp 268. Price 2*s.* 6*d.* net—An account written in a somewhat popular fashion of the uses of light, heat, electricity, and exercise in the treatment of disease. All these are useful applications and are only too often exploited by quacks, so perhaps it is well that qualified medical men should study them.

The Examination of the Urine. By J. K. WATSON, M.D., C.M. Edin London: The Scientific Press. Pp. 30—This little book is, according to the author's preface, intended for nurses but students should also find it very useful. It is divided into three parts dealing respectively with the urinary apparatus, with the characteristics of the urine both in health and in disease, and with the collection and examination of the urine. Microscopical tests are omitted as being beyond the scope of the work which, so far as it goes, is simple and very clearly written.

In Lakeland Dells and Fells. By W. T. PALMER. London: Chatto and Windus. 1903 Pp. 351. Price 6*s.*—This is a book which causes an unhappy reviewer who lives and works in London to sigh over his lot For it is a record of clean air, sunshine, clean rain, the smell of a moor on a hot day, the bleating of sheep, and the song of birds. Not that a fell shepherd's life is a sinecure like that of his fellow, of Tahiti (mentioned in the "Anti-Jacobin"), for there *are* sheep on the fells and sometimes there is snow. Mr. Palmer's book will give the town dweller a very vivid idea of the trials of a shepherd's life. Besides this Mr. Palmer talks pleasantly of foxes and rabbits, of fishing, of rock climbing and waterfowl, and many another country sight and occupation. There are portions of this little island not yet spoiled by railways, factories, and motor-cars, and long may they remain so.

Official Year-book of the Scientific and Learned Societies of Great Britain and Ireland. Twentieth annual issue. London: Charles Griffin and Co. 1903. Pp. 304.—This extremely useful work is a complement for the scientific worker to the indispensable "Whitaker." It contains full details of the constitution and working of the scientific and learned societies of these islands. The societies are divided into 15 sections. It is altogether an admirable compilation.

The Swedish System of Physical Education. By THEODORA JOHNSON. Bristol: John Wright. London: Simpkin. 1899. Pp 79.—This little book which we only received in October, 1903, is an expansion of a paper read by Miss Johnson before the British Medical Association in 1894. Swedish exercises and massage undoubtedly have a most beneficial influence in improving nutrition and in preventing or correcting deformities when they are used under careful medical supervision. Miss Johnson does not claim impossibilities for the system and we are glad to see that she lays stress upon the dangers which may accrue from massage and exercises being allowed to drift into the hands of quacks.

The Elements of Kellgren's Manual Treatment. By EDGAR F. CYRIAX, M.D. Edin. London: John Bale, Sons, and Danielsson. 1903 Pp 596.—Dr. Cyriax's work is founded upon a thesis which under the same title was accepted with commendation for the degree of M.D. by the University of Edinburgh in 1901. It gives a very complete account of Kellgren's methods as well as illustrative cases of various diseases in which the treatment was used. We cannot say that we are so impressed with its value in acute specific infectious diseases as Dr. Cyriax appears to be. It may improve nutrition and so do good but we have our doubts as to the wisdom of "heart shaking" or "side shaking" in typhoid fever or in diphtheria, which we understand Dr. Cyriax to recommend. Surely also to allow absolute freedom of diet to a patient suffering from typhoid fever is, to say the least of it, risky.

New Inventions.

THE "UNIQUE" GAS GRILLER

THE method of cooking meats by broiling or grilling has undoubted dietetic advantages, assuming that it is properly carried out. It is important, however, that grilling should be rapidly effected and that a large surface of the meat should be exposed to the direct action of a high and uniform temperature in order that the nutritive juices of the meat should be retained within its substance and also that the flavour should be properly developed. It is further desirable for obvious reasons that both sides of the meat should, if possible, be simultaneously cooked, a consummation that can hardly be attained by grilling over hot coals. By using gas, however, both sides of the meat can be cooked at the same time, but then it often, if not universally, happens that the flavour of the meat is seriously affected by the improper combustion of the gas Mr. A E. Harris of 64, Finsbury-pavement, London, E C., has devised a gas griller which, we think, completely overcomes the objection to the use of gas for grilling and which gives a uniformly fierce and "clean" heat that simultaneously cooks both sides of a steak, chop, sole, or sausage. The construction of the griller is quite simple and consists merely of a metal box, the vertical walls of which inside are so constructed as to form a burner of a certain design. The walls are hollow and of wave-like shape —thus ∿∿∿∿—and on the crest of the wave are holes at which the gas is burnt. The effect of this wave-like shape is that the gas in burning heats the supply of gas within the "wave" previously to combustion. It is as though the gas were passing through a series of tubes which are superheated. The air-supply is necessarily heated at the same time. The result is complete combustion and the absence of any smell due to the escape of unburnt products and the sulphur compounds are completely oxidised. The heat is thus intense, as is the case with all burners constructed, as this is, on the "regenerative" principle. The burner is "atmospheric." We have seen this grill in use and its action is very satisfactory. It cooks meat rapidly and perfectly and the flavour is excellent because the juices are retained and there is no suggestion of the flavour of partially burnt coal gas. During all the time the outside air is free to play over the meat as with roasting. It is well known that in order to secure the perfect combustion of coal gas both the air- and gas supply should be heated. Meat cooked by this griller is not diminished in size or "dried up" but is plump, juicy, and appetising. An ordinary steak is thoroughly cooked in five minutes and it is stated that 72 steaks can be perfectly grilled in the course of one hour at a maximum cost of 1¼*d* It is proposed to construct large grills upon this principle for hotels and restaurants It need hardly be added that the adoption of this griller on a large scale would save the production of volumes of smoke now discharged into the air from the chimneys of hotel and restaurant kitchens.

THE "FACILE" FOOD WARMER.

THIS is a very simple device by which food may be kept warm by means of an ordinary night-light. It consists of a tin stand, semi-pyramidal in shape when erect, provided with a lower platform for the night-light and an upper platform with perforations on which to place the food container. The apparatus when ready for use is about three inches high. The supports at one end may be detached while at the other end is a hinge so that the parts collapse to a flat plate which may be packed easily for travelling purposes The food warmer may be safely placed by the bedside when a night-light is used and thus it will prove very useful in the nursery or sick room. The specimen which we have described was sent to us by the Safety Letter Box Co., of 81, Denmark-hill, London, S.E., and the inventor is Miss Bishop.

AN ELECTRIC FOOT OR BODY WARMER.

THE electric current promises to be adapted to all sorts of domestic comforts; it is only a matter of economical production, but it must be admitted that in many applications electricity is at present expensive. There are one or two points about an electric foot or body warmer recently brought to our notice which recommend it. In the first place it is stated that it does not cost more than a penny for six hours' use; in the second it is so constructed that the heat is not allowed to accumulate but to disperse slowly, whilst at the same time the warmer itself keeps comfortably hot; and thirdly the apparatus may be attached to any system of supply, whether it is intermittent or continuous or at a pressure within the limits of the ordinary domestic lighting supply. With this warmer all that is necessary to be done is to place within it an eight candle power lamp identical with that used in the house. The wire "lead" terminates in an adaptor which fits into the electric light socket in the same way as a lamp, by means of a bayonet catch. The switch is then available for turning the current on to the warmer. The warmer thus serves in place of the hot water bottle or the bedpan for warming the bed or it may be used as a foot warmer or for warming garments. The warmer, which is of the shape of a stone foot warmer, is inclosed in flannel. We found that on wrapping the foot warmer in an overcoat or on placing it in the bed while warmth is steadily maintained it never approaches a point of risk. The eight candle-power lamp is exactly suited to the requirement. The price of this warmer is 21*s.* nickel-plated, 17*s.* 6*d.* in brass or copper, and 15*s.* in tin, and the manufacturer is Mr. W. Back, 166, Queen's-road, Bayswater, London, W.

DATE

SURGEONS WHO HAVE WON THE VICTORIA CROSS.

Compiled by G. F. Blake.

Registrar of the Royal College of Surgeons in Ireland.

The Victoria Cross was instituted by Royal Warrant, Jan. 29th, 1856. *It is provided that not rank, or long service, or wounds, or any other circumstances whatever, save the merit of conspicuous bravery or devotion to the country in the presence of the enemy, shall be held to establish a sufficient claim to the honour.* Since its institution less than 500 crosses have been conferred, 26 of which have been awarded to surgeons. The following notes show how each of these 26 distinguished members of the medical profession obtained the coveted decoration:—

William Babtie, Major, now Lieutenant Colonel, R A.M.C., C.M.G., M.B. Glasg. 1880, L.R.C.P. and S. Edin. 1880, was awarded the Victoria Cross for going out and attending wounded exposed to heavy fire and afterwards going out, also under heavy fire, and bringing in Lieutenant Roberts who was lying wounded on the veldt. "Colenso, South Africa," 1899.

William Bradshaw (deceased), Assistant Surgeon 90th Regiment, L.R.C.S. Irel. 1854, was awarded the Victoria Cross for gallantly defending the wounded left under his charge and was himself wounded. "Lucknow, Indian Mutiny," 1857.

Thomas Joseph Crean, Surgeon-Captain 1st Imperial Light Horse, now Captain R.A.M.C., L.R.C.P. & S Irel. 1895, Hon. F.R.C.S. Irel. 1901, was awarded the Victoria Cross for conspicuous gallantry in continuing to attend wounded in the firing line under heavy fire at 150 yards range when he was himself wounded, and only desisted when he was hit a second time. "Tygerskloof, South Africa," 1901.

John Crimmin, Surgeon, now Lieutenant-Colonel, I.M.S, C.I.E., L.R.C.P. Irel. 1882, L.R.C.S. Irel. 1879, was awarded the Victoria Cross for attending wounded actually within the enemy's fighting line, and had at one time to leave his charge and to fight hand to hand against heavy odds, killing one man with his sword. When help arrived the enemy were driven off. "Burma, India," 1889.

Campbell Millis Douglas, Assistant Surgeon 24th Regiment, now Brigade-Surgeon A.M.D. (retired), M.D. Edin. 1861, L.R.C.S Edin. 1861, Silver Medal Royal Humane Society for saving life at sea, was awarded the Victoria Cross for his gallant and daring manner in taking boat through dangerous sea and rescuing 17 officers and soldiers. "Little Andaman Island," 1867.

Henry Edward Manning Douglas, Lieutenant R A.M.C, D.S.O., L R.C.P. Edin. 1898, L.F.P. & S. Glasg. 1898, was awarded the Victoria Cross for having shown great gallantry and devotion under severe fire in the open in attending a wounded officer and on the same day attending another wounded officer and men under a fearful fire. "Magersfontein, South Africa," 1899.

Thomas Egerton Hale, Assistant Surgeon 7th Regiment, now Surgeon-Major A M.D. (retired), J.P., M.D. St. And. 1856, M.R C S. Eng. 1854, was awarded the Victoria Cross for remaining with a wounded officer and bringing in wounded under fire. "Sebastopol, Crimean War," 1855.

Edmund Baron Hartley, Surgeon-Major Cape Mounted Rifles, now Surgeon-Lieutenant-Colonel, Colonial Forces, Cape Colony, C.M.G, L R C.P. Edin. 1880, M.R.C S Eng. 1874, was awarded the Victoria Cross for attending and carrying wounded to a place of safety under fire. "Basutoland, South Africa," 1879.

Anthony Dickson Home, Surgeon 90th Regiment, afterwards Surgeon-General, A.M.D. (retired), K.C.B., M.D. St. And. 1847, was awarded the Victoria Cross for persevering bravery and admirable conduct in defending the wounded left under his charge. "Lucknow, Indian Mutiny," 1857.

Neville Reginald Howse, Captain New South Wales Medical Staff Corps, L.R.C.P. Lond. 1887, M. 1886, F. 1897, R C.S. Eng., was awarded the Victoria Cross for going out under a heavy cross fire and carrying a wounded man to a place of safety. "Vredefort, South Africa," 1900.

Edgar Thomas Inkson, Lieutenant, now Captain, R.A.M.C., L R C.P. Lond. 1898, M R C.S. Eng. 1898, was awarded the Victoria Cross for having carried a wounded officer over exposed ground to a place of safety under heavy fire. "Tugela, South Africa," 1900.

Joseph Jee (deceased), Surgeon 78th Regiment, afterwards Deputy Inspector General A.M.D., C.B, M.R.C.S. Eng. 1841, winner of the Grand Prix du Casino, Monte Carlo, 1873, was awarded the Victoria Cross for gallantry in attending, protecting, and saving a number of wounded. "Lucknow, Indian Mutiny," 1857.

Ferdinand Simeon Le Quesne, Surgeon A.M.D., now Major R.A.M.C, L.R.C.P. Lond. 1886, M.R.C.S. Eng. 1886, L.S A. Lond. 1885, was awarded the Victoria Cross for attending a wounded officer in front of the enemy's loopholes and attending another officer under heavy fire when he was himself wounded. "Burma, India," 1889.

Owen Edward Pennefather Lloyd, Major A.M.D., now Lieutenant-Colonel R.A.M.C., L.R C.P. Edin. 1877, L.R.C.S. Edin 1877, was awarded the Victoria Cross for conspicuous bravery in going to rescue a wounded officer under heavy fire. "Kachin Expedition, India," 1894.

[illegible] Surgeon Cape Mounted Pc [illegible] .C.P. Edin. 1878, was av [illegible] nding wounded under heavy fire, although himself wounded, and carrying wounded to a place of safety under fire. "Transvaal War, South Africa," 1881.

Valentine Munbee McMaster (deceased), Assistant Surgeon 78th Regiment, M R C.S. Edin. 1855, M.D. Univ. Edin. 1860, was awarded the Victoria Cross for attending to, and bringing in, wounded under a heavy fire and was himself wounded. "Lucknow, Indian Mutiny," 1857.

William Job Maillard (deceased), Staff-Surgeon Royal Navy, M B 1888, M D. 1891 Lond. Univ., M.R C.P. Lond. 1888, M.R.C S. Eng. 1888, was awarded the Victoria Cross for going through a perfect hail of bullets and endeavouring to rescue a wounded seaman of H.M.S. *Hazard.* "Island of Crete," 1898.

[illegible]

Arthur Martin [illegible] Constabulary, L. [illegible] was awarded the [illegible] under a heavy fire at 100 yards range and assisting a wounded officer to a place of safety when he was himself shot three times. "Vlakfontein, South Africa," 1901.

[illegible] af [illegible] of [illegible] the Victoria Cross for rescuing wounded officer from [illegible] and binding his wounds in the presence of [illegible] n War," 1854.

[illegible] ckerson, Lieutenant, now [illegible] 1896, Victoria University, Manchester, was awarded the Victoria Cross for going out and attending wounded man under a heavy rifle and shell fire, dressing his wounds and remaining with him till he was removed to a place of safety. "Wakkerstroom, South Africa," 1900.

Herbert Taylor Reade (deceased), Surgeon 61st Regiment, afterwards Surgeon-General A.M.D., C.B, M.R.C.S. Eng. 1849, was awarded the Victoria Cross for gallantry in dislodging with small force party of rebels firing on wounded. "Delhi, Indian Mutiny," 1857.

James Henry Reynolds, Surgeon Major, now Lieutenant-Colonel, A.M.D. (retired), M.B., M.Ch. Univ. Durh. 1867, Hon. F.R.C P. Irel. 1879, was awarded the Victoria Cross for conspicuous bravery in attending the wounded under fire and defence of hospital. "Rorke's Drift, Zululand, South Africa," 1879.

Henry Thomas Sylvester, Assistant Surgeon 23rd Regiment (retired), Knight of the Legion of Honour, M.D. Aberdeen 1855, L.R.C.S. Edin. 1853, L.S.A. 1869, was awarded the Victoria Cross for going out to a wounded officer and attending wounded under heavy fire. "Sebastopol, Crimean War," 1855.

William Temple, Assistant Surgeon Royal Artillery, now Brigade Surgeon A.M.D. (retired), M B. Univ. Dub. 1858, L.R C.S Irel. 1858, was awarded the Victoria Cross for gallant conduct and devotion in assisting wounded under heavy fire. "Maori War, New Zealand," 1864.

Harry Frederick Whitchurch, Surgeon-Captain, now Major, I.M.S., L.R.C.P. Lond. 1887, M.R.C S. Eng. 1887, was awarded the Victoria Cross for rescuing a wounded officer when the troops with which he was fell back, having to proceed over a mile under the enemy's fire. "Chitral, India," 1895.

THE LANCET.

LONDON: SATURDAY, JANUARY 9, 1904.

The Dental Requirements of the Army.

The recent war in South Africa brought vividly before the military authorities the importance of insuring that the teeth of soldiers on active service should be in an efficient condition. The question has attracted for many years the attention of the dental profession and the notice of the War Office was drawn to it by the British Dental Association and others in the years previous to the outbreak of war. At the commencement, too, of the campaign dental services were volunteered but not accepted, and it was not until the subject was brought forcibly home by the large number of men invalided on account of dental disease that a move was made by the appointment of 12 civil dental surgeons—a number totally inadequate for the forces in the field.

The question of the dental requirements of the army is, we believe, engaging the notice of the War Office and it is to be hoped that some workable scheme will be forthcoming. The subject is, however, beset with many difficulties and there are many issues to be considered. In the first place it is essential that those responsible for any scheme should have some knowledge of the amount of time and physical exertion which dental operations entail, and some idea should be obtained of the number of hours of work likely to be required to keep the teeth of a definite number of men in order. For this purpose statistics might be obtained from those trained in dental surgery. Without a definite basis to work upon it will be impossible to formulate a really efficient scheme. Again, the scope of services to be rendered must be defined. A very large majority of the recruits require a considerable amount of dental attention. At the present time nothing is done to place their mouths in order and to keep them in a state of efficiency, with the result that, although the soldiers on enlistment may have a sufficient masticating apparatus, in the course of time it is likely to be impaired considerably by the ravages of dental caries. This condition of affairs, as the recent campaign showed, proved to be a serious waste in the fighting strength of the army and from a commercial aspect a serious monetary loss. A large amount of this loss could have been avoided by insuring that the mouths of all men on active service were in a condition capable of dealing with their rations and were also free from all sources of sepsis; the removal alone of septic roots and teeth previously to active service would have avoided a large amount of dental sickness. The experience of dental practitioners is that men and officers who served during the campaign and who had their teeth placed in proper order suffered little from dental troubles. There can therefore be little doubt that the efficiency of the army would be considerably enhanced by insuring that the mouths of all soldiers were in thorough order. A man on being accepted as a recruit should, during his period of training at the depôt, have his mouth properly treated and should be given instruction in dental hygiene. If this is done it will require but a comparatively small expenditure of time to keep his teeth in a proper condition, providing that he receives attention at regular periods and shows himself willing to be helped.

Roughly speaking 50 000 recruits are enlisted each year, and as it is more than possible that at least two hours' work would be necessary for each recruit the services of between 60 and 70 dental surgeons would be required for this branch of the work alone. These figures are probably well within the mark, and the only way in which a trustworthy estimate of the time and services required can be obtained is by a thorough investigation of the subject. In considering the means for carrying out the dental requirements of the army there is the possible difficulty of obtaining a sufficient number of qualified dental surgeons Work involving elaborate technique would, however, not be called for, and the main operative treatment would consist in the removal of teeth and the insertion of plastic fillings. This work could be to some extent carried out, it is suggested, by the Royal Army Medical Corps if officers entering that service were compelled to pass through a course of instruction at one of the dental hospitals; while for the treatment of the recruits and special cases qualified dental surgeons could be appointed to the different military centres. But we are not prepared offhand to advocate any increase of the multifarious duties of the Royal Army Medical Corps. Nor do we suppose that the department will consider the present a favourable season for making these officers compulsory dental students. The question requires careful thought and we cannot help feeling that in the elaboration of any scheme the advice of a practitioner of dental surgery would probably prove of considerable assistance to the authorities.

◆

The Scottish Poor-law Medical Service.

On many occasions attention has been called in our columns to a serious anomaly peculiar to the Scottish Poor-law service—namely, the insecurity of the medical men in their tenure of office—and a case of which mention was made in The Lancet of Dec. 19th, 1903, p. 1758, induces us to return to the subject. It is well known that in England and Ireland the appointments of Poor law medical officers are made by the local bodies—i.e., parish councils or boards of guardians—but the appointments once confirmed are not terminable at the instance of these boards or councils without the express sanction of the Local Government Board in either London or Dublin. In Scotland, on the other hand, the position of affairs is quite different, for a Poor-law medical officer holds office entirely at the discretion of the parish council or board of guardians which has a legal right to dismiss him of its own initiative without alleging any offence on his part or otherwise justifying its action. To a certain order of mind the simplicity of this arrangement might seem to be a recommendation, but a moment's reflection would suggest that an authority so extensive might sometimes degenerate into an arbitrary despotism, and experience shows that this is so. The most recent victim of this policy is Dr. J. F. D. MACARA of Durness in Sutherlandshire, who has been medical officer of that parish for several years. It is easy to understand that he may not have been a *persona gratissima* in the eyes of his late employers, for he has been largely instrumental in making known the grievances of the Poor-law medical service, and in THE LANCET of Dec. 23rd, 1899, p. 1776, we published a letter from him in favour of the movement for granting a stated annual period of holidays, the locum-tenent to be paid by the parish. This object is a very reasonable one, for a medical practitioner holding such an appointment cannot absent himself without providing a substitute and in the sparsely populated districts of northern Scotland no one in a position to take his place might be accessible within a radius of many miles. The crowning achievement of a parish council bent on harassing a medical officer was perhaps that which came to pass, or at least had its origin, in South Uist, one of the many islands on the west coast of Scotland. Mr. J. LAMONT, the Poor-law medical officer of that island, was dismissed from his appointment in July, 1898, for some reason to which no prominence was given but which apparently arose out of a dispute as to the closing of a school during the prevalence of an epidemic. In the following September he was arrested at night in his mother's house in Glasgow, lodged in prison for two days, conveyed under a police escort to South Uist, and eventually sent for trial to the county town, Inverness, where the jury acquitted him. The charge brought against him was that after vaccinating infants at places very remote from his residence he did not make a second journey to inspect the vesicle but gave certificates of successful vaccination on information supplied by some intelligent inhabitant of the locality in question. The accused had no difficulty in showing that his offence was venial and that the same system was followed by other vaccinators whose patients were scattered over wide areas. Copious details of Mr. LAMONT'S case and a report of the debate in the House of Commons to which it gave rise are to be found in THE LANCET of 1899. The obvious moral is that legislation is urgently required investing the Local Government Board of Scotland with powers of intervention and veto in the dismissal of Poor-law medical officers so that there may be uniformity of procedure in the three divisions of the kingdom.

Housing of the Poor in Dublin.

THE question of the proper housing of the working classes, which has for several years been prominent among the problems of municipal government in London and in many English provincial cities, has reached its most acute stage in Dublin. Readers of THE LANCET, recalling the communications of our Special Sanitary Commissioner as well as our weekly letter from Dublin, will not be surprised to learn that an unfortunate condition of things exists in the Irish capital. We have before us an official report of a conference on the subject between the Parliamentary representatives of the county and city of Dublin, the corporation of Dublin, and the Dublin Trades Council, which discloses conditions to which it is probable no parallel can be found elsewhere and that call urgently for reform in the interests alike of health and of decency. In a population of 292,000 persons, in which there were 59,263 families containing an average of 4·6 persons in each, it was found in 1901 that 21,702 of these families occupied only a single room and that 13,620 occupied only two rooms; in other words, 162,481 persons lived, ate, and slept in 48,942 rooms, and the report asserts, we hope with absolute accuracy, that "no such state of things, or anything approaching to it, exists in any other town in the United Kingdom." Endeavours have been made, by the corporation of Dublin, by the large minded charity of Lord IVEAGH and of Messrs. ARTHUR GUINNESS and Co., and by the energy of the Great Southern and Western Railway Company and of some building companies established for the purpose, to meet the requirements of the case, but possibly because the evils described have been suffered to accumulate for a long period these endeavours have not yet been able to overtake or to cope with them. It is manifest that a large population housed in the manner described must be a standing menace not only to the health of the community but also to law and order, and it would be difficult to conceive the existence of any "injustice to Ireland" of a more flagrant character than that of suffering such an abuse to continue unrelieved. The city contains a large number of insanitary areas and some absolutely derelict spaces, all of which might be covered with new dwellings; but which, even if they were entirely utilised, would soon be insufficient to meet the ever-increasing demands of the population. The committee appointed to inquire into the subject is unanimously of opinion that it is necessary to build cottages or self-contained dwellings on the outskirts of the city and to provide cheap means of transit to and fro for workers. In order that this may be done it asks for a simplification of the laws relating to the acquisition of land and for a considerable prolongation of the time over which the repayment of municipal loans for building purposes may be extended, expedients to which it has already been found necessary to have recourse in England. The extension of the repayment of loans over long periods is a course by no means to be adopted without grave consideration, since it unquestionably opens the door to many abuses in municipal government, but there are many conditions, and those now existing in Dublin appear to be examples of them, in which it would clearly be the lesser of two evils. The city is not rich enough to attempt the speedy removal of the consequences of accumulated neglect unless ample time can be given for the repayment of the principal sums required and for some recoupment from the rents of the new buildings which must be erected.

In view of the condition of overcrowding disclosed by the report it is not remarkable that the annual death rate per 1000 living during the third quarter of 1903 was 18·9 in Dublin, as against 14·1 in London, 14 6 in Edinburgh, 16 2 in Glasgow, and 17·3 in Belfast. In round numbers this means that 1460 people die every year in Dublin who, if they had been placed in the better sanitary conditions of London, would have remained alive. In dealing with the typhoid epidemics at Belfast[1] we clearly showed that the insalubrious conditions of that city could well place it next to Dublin and above Glasgow in its death-rate. Even among the better classes the standard of domestic cleanliness and comfort is not so high in Ireland as in England; and the toleration of poultry and of "the gintleman that pays the rint" and his family in the cabins of the rural peasantry is not entirely without parallel in the general untidiness of many homes in which the pressure of poverty cannot be pleaded as an excuse for their condition. Even with a people naturally cleanly in their habits overcrowding would mean dirt, and dirt would mean disease; and where it unfortunately happens that cleanliness is very little regarded the consequences are bound to follow in a still more pronounced degree. The state of things described by the report to which we refer must to a great extent neutralise the best efforts of sanitary reformers in Dublin; and is amply sufficient to occasion, not only by reason of epidemic prevalences, but also by its effect in lowering the general standard of health among the population, the condition of the death-rate which the Registrar-General records. It is unquestionably high time that the subject received the attention of the Legislature. It is not one which is likely to commend itself to demagogues, and there is therefore all the more reason why the necessary reforms should be urged forward by the voices of the medical profession, and by those of all educated people who desire at once to ameliorate the condition of their poorer neighbours and to remove a source of manifest danger alike to the physical and the moral health of the community.

---

[1] See THE LANCET, Nov. 19th and 26th and Dec. 10th and 31st, 1898.

It is hardly possible without the guidance of complete local knowledge to form an opinion as to the character and the sufficiency of the methods suggested for dealing with the evils disclosed by the report; but in December, 1899, and January, 1900, we published a series of articles setting forth the insanitary conditions of Dublin and explaining how so many "derelict" houses and spaces have come into existence. A few years ago streets or spaces which might be described as "derelict" were to be seen here and there in London and it was usually said or imagined that they were "in Chancery," but the report tells us that, as might have been expected, some of the overcrowding of Dublin is due to the falling to pieces of old habitations which it seems to be nobody's business to rebuild or to repair. Since 1879 more than 3000 houses have been "detenanted" and closed, and although many have been rebuilt or improved many more are either in ruins or have disappeared. At present there are in Dublin 302 derelict houses, 148 houses in complete ruin, and derelict spaces on which 82 houses formerly stood—in all, 532 houses. Some of the derelict houses and ruins are the property of the corporation and with regard to these, we presume, nothing but the want of available means could prevent the spaces which they occupy from being utilised. It is quite conceivable that, especially with the Irish love of litigation, any attempt to use or to improve derelict property might call forth numerous claimants and might entail considerable and utterly useless expense. The extension to Ireland of some of the provisions of the English law, as suggested in the report, would suffice to overcome many impediments of which we in this country have had practical experience; and it surely would not be impossible to devise some simple method by which the rights of *bonâ fide* owners of the soil might be protected, or compulsorily acquired at equitable rates by the corporation or by a building company, in cases where pieces of land are unoccupied or are covered only by ruinous remains. The Local Government Board, or some kindred body, might easily be empowered to prevent unjust confiscation; but it is manifest that no scruples of a merely red-tape description should be suffered to prevent the abatement of a public nuisance or the reform of conditions disgraceful to civilisation and injurious to the welfare of the public.

Annotations.

"Ne quid nimis."

RADIO-ACTIVITY OF THE ANIMATE AS WELL AS THE INANIMATE.

IT is impossible to review the exciting and intensely interesting situation to which the discovery of radio-active emanations has brought scientific thought without feelings of the deepest wonder. Almost every day sees discovery added to discovery and phenomena are disclosed which threaten to render obsolete the use of the word occult. Facts are rapidly being presented before time has been given to formulate a theory which will explain them and the faculty of imagination was never so active in attempting to break down the barrier between the psychical and the tangible. We no sooner recover from the excitement of the discovery of the *x* rays and the remarkable phenomena related to them, than the atom is announced to be after all not the finitely small but a tiny system swarming with electrons. The discovery of radium and its remarkable properties comes, so to speak, in the nick of time to clinch the argument and for the first time scientific men are able to say, "We have actually touched the borderland where matter and force seem to merge into each other." Barely a moment is left to ponder over this stupendous revelation before it is announced that the transmutation of one element into another has been ascertained for certain to take place. In the meantime investigation apparently in an entirely different field has brought some French chemists to state positively that an imprint of the dead Christ, revealing the manner of his death and passion, is apparent upon the Holy Shroud of Turin. Their explanations appeared to be crude and referred to the action of emanations from the dead body upon the embalming materials of the sheet. The outline of the dead Christ upon the shroud was regarded as a "vaporographic print." In these days of the announcement of new active rays, emanations, vapours, etheric vibrations, electrons, or whatever we may choose to call them, the explanation may be different and more exact. In several communications to the Académie des Sciences M. Blondlot, for example, has lately described what appears to be yet a new grouping of active rays for which he suggests the designation "n" rays. These rays have the property of augmenting the brightness of a phosphorescent substance such as platino-cyanide of barium the luminosity of which has been appropriately adjusted by exposure to a salt of radium. They are able to traverse metals and other opaque bodies and appear to be given off by most sources of light and heat, including the sun. Further, they are able to be brought to a focus by means of a lens of glass or by one consisting of an aluminium shell containing a solution of salt. While studying Blondlot's rays M. Aug. Charpentier observed that emanations of a similar character were emitted by the human body and that the effect produced upon a sensitive screen placed at a little distance was proportional to the physiological *activity of the part, being greatest in the case* of muscle and nerve. By using a small screen and noting the variation in luminosity which it exhibited he found it possible to map out the area of the heart and to trace the course of nerves beneath the skin. That the phenomena were not due to heat simply was shown by interposing screens of aluminium or glass, which did not affect the result, nor could the rays be supposed to have been previously absorbed from some external source since the manifestations were obtainable equally well after the part of the body under observation had been kept in darkness for nine hours. As yet it does not appear that this method of investigation has more than a theoretical value, but the same might have been said of the early stages of almost any application of scientific methods and it is possible that the researches of M. Charpentier may have far-reaching consequences. In an annotation in THE LANCET of April 26th, 1902, p. 1216, we hazarded the question, "*Does the human body possess* properties akin to radio-activity?" The researches of M. Charpentier would appear to indicate clearly that it does.

THE ARMY MEDICAL SERVICE: PRESENT AND FUTURE.

NOW that the Report of the Royal Commission on the War in South Africa with its accompanying minutes of evidence has been widely read and discussed it may not be without interest to our readers if we call their attention to some remarks which appeared in our Annus Medicus for 1900. Speaking of the war then going on in South Africa we referred to some of the lessons to be learned from our experience in that campaign in regard to the medical services of the present and the future. "It is impossible," we said, "*for financial reasons to* maintain in time of peace a Royal Army Medical Corps at a strength and on a scale adequate for the requirements of a big war. That the corps as it exists at present must be largely increased and that its officers must have increased facilities for professional study and training is obvious. The way in which this can be best accomplished must be considered hereafter. A radical and comprehensive reorganisation will be necessary for the purpose. But some scheme in the nature of the German system of keeping the civil medical element in touch with the army will also have to be introduced, as well as a method of welding all branches of the medical service—militia and volunteers—with the regulars and of giving all their members some training in military medical duties. The war in South Africa has opened a new chapter in the history of the British Empire by closely cementing the colonies with the motherland; and we have now to frame an organisation by which the whole strength of the medical element at our disposal can be made available in war. The aim in our future wars will rather have to be to take the hospital to the wounded than the wounded to the hospital. The field hospitals will require to be treated as independent units in every respect and to be furnished with adequate transport, and the bearer columns will probably have to be attached to, and utilised by, these hospitals. A more easily-working and active organisation will also have to be given to stationary hospitals to enable them to change their position and to move when and where they are required. The hospital nursing system will have to be largely increased and better provided for; but we do not believe that it is practicable or expedient to have female nurses with the moveable hospitals in the immediate track of the front fighting line. As regards the men of the Royal Army Medical Corps, it has always seemed to us that every attention should be given to their hospital training as orderlies and nurses and that their military training in the way of parades and inspections should be curtailed as much as possible. The usefulness of such men lies in the former direction—as properly qualified attendants on the sick and wounded—and not in their acquaintance with military drills or their smartness as soldiers. The question of the organisation of a special service with a large sanitary executive for the carrying out of practical army hygiene will have to be considered and settled. There is much besides—such as having an army medical school in London instead of at Netley—affecting the medical service and all that appertains thereto which will have to be taken up in earnest in the coming army reforms, but whatever is done must be done deliberately and in time of peace." Very much of all this, as our readers know, has been carried out already. To the foregoing summary statement of what we then regarded as the main requirements it seems desirable to make a slight addition in order to make it a fairly complete one for the present time. In a campaign provision should be made for advanced medical depôts to advance, as far as practicable, with the forces in the field for the *twofold purpose of replenishing field hos*pitals with supplies of medical and surgical stores and of relieving them whenever desirable of the transport of any unnecessary stores. These advanced medical store depôts should be in charge of a field medical storekeeper and should be provided with a packer, a carpenter, and a cutler as laid down in the "Field Service Medical Manual for the Indian Army." The adoption on field service of some system for the movement and location of such depôts at various convenient and accessible points would be attended with manifest advantages.

PROXIMUS ARDET UCALEGON.

THE appalling disaster which occurred at Chicago on Dec. 30th when the Iroquois Theatre took fire during the performance of a matinée has resulted in 588 persons losing their lives. Panic and not burning would seem to have been the principal cause of such a loss of life, one which exceeds that of any other theatre fire except that which occurred at the Ring Theatre, Vienna, in 1881 when 600 lives were lost. It is useless to speculate upon what further precautions might have been taken as regards the structure of the building. The theatre was quite new and was built on the most modern principles, being as "fire-proof" as it was possible to make it. There were in all 40 exits but, and this is a most important point, the doors of the emergency exits had never been opened and were not only locked but were rusted in their frames. So says the Chicago correspondent of the *Daily News* of Jan. 1st, while the Chicago correspondent of the *Times* of the same date states that the asbestos curtain between the stage and the auditorium had never worked properly during the five weeks that the theatre had been open. Panic, of course, neutralises every effort that may be made by builders, municipal authorities, or managers to render theatres safe, but nevertheless someone on this occasion must have blundered. The London County Council has done excellent work in safeguarding theatre-goers from fire but there is one London theatre at least where one portion of the house is in a most unsatisfactory condition and that is the amphitheatre in Covent Garden Theatre. Exit from or entrance to, these seats is obtained either by passing between the rows of chairs, which rows are placed very near together on a steep set of "gradines," or else by passing under the amphitheatre seats through a narrow passage like those in the Catacombs. What would happen here if there were a fire is awful to contemplate and the arrangement should certainly be altered. Another point to which we draw attention is the notice frequently seen in London theatres, "Extra exit to be used in case of necessity only" or words to that effect. Now this should not be allowed. Every exit should be able to be used at every performance. Extra exits which are supposed to be used only in cases of emergency are when the time comes either found to be unusable or are not known to exist. The Chicago fire, as do most calamities, gave rise to both heights of heroism and depths of selfishness. There is no need here to recapitulate the heroism of Mr. Foy, the actor, or of the Right Reverend — Muldoon, the Roman Catholic Bishop of Chicago. The heartless conduct of the livery-stable drivers who being on strike refused to drive the dead and the injured to the hospitals seems incredible. If this report be true we do not think that Chicago will forget the occurrence in a hurry. Messages of sympathy have already passed from His Majesty the King and from the official representatives of us Britons to our kin beyond the seas and we can but add our condolences. The new year opens mournfully for Chicago and the saddest feature of the catastrophe is that a large proportion of the victims is made up of children.

"Quos dulcis vitae exsortes . . . .
Abstulit atra dies."

THE FAT BOY OF PECKHAM.

Mr. Hopkins, sitting at the Lambeth police court, has held that Johnnie Trundley, known to the public as the Fat Boy of Peckham, when he appears for the purpose of exhibiting his abnormal proportions upon a music hall stage is not playing or performing for profit and that consequently his so appearing is not to be forbidden under the Act for the Prevention of Cruelty to Children, 1894. This decision should settle the question of this obese infant's education, for so long as he can attract the curious to gaze upon him he will, presumably, be able to reside in the metropolis or to tour the country according to his engagements in the charge of a governess or a private tutor, instead of being consigned to the care of the public education authority. For the present, at all events, he will also be able to earn his living, and it is to be hoped that some portion of his emoluments will be set aside to provide for the time when he may have passed the zenith of his fame. He is certainly a child of very unusual development, even for cases such as his. In THE LANCET of July 19th, 1890, p. 161, we published the letter of a correspondent which gave the following figures with regard to a boy aged five and a half years. Height, 4 feet; weight, 8 stones 5 pounds; circumference of abdomen, 42½ inches; waist, 37½ inches; chest, 37 inches; neck, 14 inches; head 22½ inches; thigh, 23 inches; calf, 15½ inches; arm, 11½ inches; and forearm, 10½ inches. We have not before us the particulars relating to young Trundley, but as he was stated at the police-court to be five years of age and to weigh 10 stones 4 pounds they may be assumed to exceed those quoted. The attention aroused by the Peckham child has nothing new or surprising about it. Every travelling showman would testify that obesity has always been at least as highly appreciated by the public as abnormal stature, and the youthful Trundley has had the advantage, or the disadvantage, of living in an age in which notoriety is easily achieved. Even in these circumstances it is doubtful whether his fame as well as his vast proportions were not exceeded long before the days of halfpenny newspapers and cheap music-halls. He "cuts" no "record" in respect of size but is beaten in that respect by popular heroes and heroines who flourished more than a century ago. The "Encyclopædia Britannica," referring to an authority which we have not been able to verify, mentions a girl who at four years of age weighed over 18 stones. In "Cursory Remarks on Corpulency" by William Wadd, surgeon, published in 1816, we find recorded the death of "the surprising Worcestershire girl" who at five years old was 4 feet in height, 4 feet 2 inches round the breasts, and weighed nearly 16 stones. The same authority also mentions a seven-year-old boy in Paris who weighed 15 stones 10 pounds. In the matter of fame it will be long before the name of Trundley surpasses that of Daniel Lambert which has become almost a part of the English language. Daniel was born at Leicester in 1770 and died in 1809 at Stamford. The grandson of a celebrated cock-fighter and addicted to sport throughout his life his dimensions were not extraordinary and his habits were not different from those of other lads until he was 14 years old. When 23 years of age, however, he turned the scale at 32 stones and although he is recorded to have been then able to walk from Woolwich to London at the time of his death in his fortieth year he had attained the prodigious weight of 52 stones and was more or less helpless. He was a modest man and when he had achieved physical greatness fame was thrust upon him. He was for long unwilling to be made a show of but he gained a more than local reputation and people travelled from far to see him, resorting to various devices in order to be allowed to do so. At length the prospect of profit overcame his resolution and for four years before his death he exhibited himself in London and in the provinces. He was apparently a man of some wit, for once before he permitted the public to gaze upon him an inquisitive person had gained access to his presence by pretending to be a fellow sportsman interested in the pedigree of a mare, whereupon Lambert promptly replied, "She was bred by Impertinence out of Curiosity." In these respects, as well as in his dimensions, he has set an example which Master Trundley will not find easy to surpass. Before the days of Daniel Lambert Edward Bright of Malden was a well known fat man, although his name no longer lingers as a household word. He died in 1750 at the age of 30 years weighing 42 stones 7 pounds and is stated to have been "an active man till a year or two before his death, when his corpulency so overpowered his strength that his life was a burden and his death a deliverance." He was married and "left a widow big with her sixth child." Both Bright and Lambert seem to have been genial, good-humoured fellows, very popular among those who visited them; indeed, popularity seems to be the lot of the corpulent in fact as well as in fiction. The heroes of fiction, however, have the advantage in the matter of lasting glory and the names of Daniel Lambert and the fat boy of Peckham sink into insignificance beside those of Falstaff and the fat boy in "Pickwick."

MORE SUBSTITUTION.

FRESH disclosures appear almost every day in regard to the expanding practice of substitution. Foods, drugs, wines and spirits, and articles of clothing are all submitted to the impudent process, and according to representations recently made to us by a large firm of makers of meat foods and extracts the same kind of imposition is being practised by selling as extract of meat a preparation of yeast. It is well known, of course, that by a process of peptonisation an extract may be made from yeast cells which resembles extract of meat in chemical composition. Thus such an extract contains albumose, peptone, albumins, and extractives, and doubtless, on that account, possesses distinct nutrient value, but these facts can never justify the description of the preparation as extract of meat and it is infamous to state on the label that it is made from finest beef only. But surely there is a remedy for such an obviously false description. Chemical analysis would appear to be able easily to bring the fraud to light since genuine meat extracts give no appreciable result when added to alkaline copper solution, while yeast extract gives an abundant precipitate of a bluish-white colour. To some extent this test enables an approximate estimation of the amount of added yeast extract to be made. When—and we are weary of asking the question,

—is the fraud of substitution, which is rapidly reaching serious dimensions, going to receive the attention of our legislators? If the bakers are compelled according to the provisions of the Bread Acts to mark with the letter "M" all bread which contains potato flour or something which is not wheat, why cannot some such system be extended to every article, be it food, drink, or clothing, which is not the genuine thing but a substitute for it?

THE DIFFERENTIAL DIAGNOSIS BETWEEN MALIGNANT AND BENIGN TUMOURS.

Professor J. B. Farmer read before the Royal Society on Dec. 10th, 1903, a paper, a full *résumé* of which was published in THE LANCET of Dec 26th, 1903, p. 1830, dealing with an important series of observations which, in conjunction with his collaborators—Mr. J. E. S. Moore and Mr. C. E. Walker—he has made on the subject of malignant growths. These researches go to show that the cell proliferation of cancerous neoplasms is characterised by a nuclear division which is distinct and distinguishable from that which is common to cell proliferation in ordinary tissue growth or in benign tumours. The particular form which is found according to these researches in all malignant growths so far examined, resembles in its essential cytology that which is met with in reproductive tissue. Without entering into details it may be stated generally that the proliferating cells which are typical of malignant growths pass through a stage of nuclear division which is technically known as heterotype mitosis. This heterotype mitosis, which also occurs as a phase in the history of the development in sexual cells, shows prophases of development in which the chromosomes instead of appearing as delicate thin rods or V's split longitudinally, to present the appearance of short thickened loops or rings. Further, these chromatic loops or rings are arranged lengthwise along the spindle and ultimately divide transversely instead of longitudinally as is normally the case in nuclear division. When once this heterotype mitosis has supervened in the progress of cell proliferation all the daughter cells arising from such heterotype division contain a reduced number of chromosomes. All these stages were beautifully illustrated by microscopic sections under high-power objectives and by lantern projections. Divested of its envelope of cytological nomenclature the type of nuclear division which these observers have found in malignant growths may be said to be the same as is found in the developmental stages of ovaries and testes, with the difference, however, that the series of metamorphic phases stops short of the phase at which true sexual cells—ova and spermatozoa—are produced. One of the great points of interest which attaches to these observations is that their essential features were not discovered by accident. They were anticipated and expected from the analogy of vegetable growths and from the characteristic appearance of apogamous and aposporous reproduction in ferns. Apart from the enormous advantage which the recognition of heterotype mitosis in new growths confers in the differential diagnosis between malignant and benign neoplasms Professor Farmer and his colleagues have furthered pathological progress by indicating a direction in which future researches with regard to the pathogenesis of cancerous growths may be pursued. Were it permissible at this early stage of these important investigations to speculate on the various factors which determine as it were the reversion on the part of somatic cells to a condition which closely resembles the prophase stages of sexual cells, considerations of loss of specialised function, due to hyper-stimulation in presence of adequate nutrition, might suggest a reason for this overflow of energy in the direction of reproductive growth. The conception of malignant neoplasms as predatory and independent organisms carrying on a parasitic existence in the tissues of their host is by no means new; in fact, it is as old as the word "cancer" itself. This in no way detracts from the independent originality of the work of Professor Farmer, Mr. Moore, and Mr. Walker.

MILK AND TUBERCULOSIS.

A FEW years ago the propagation of tuberculosis through the ingestion of the milk of tuberculous cows, or at least of such as suffered from tubercle of the udder, was looked on as established beyond dispute. The possibility of infection by this means had been proved experimentally on cattle and rodents, and the alleged increase of mesenteric tuberculosis among children, concurrently with the decrease of the mortality from every other form at all ages, was held to be the strongest possible confirmation. So firm was the conviction that on the strength of it Bang elaborated his procedure for the elimination of infected animals from herds and heavy losses were gladly incurred by owners of all classes in all countries for the purpose of being able to claim that their stocks had been tested and found free from all taint. But quite recently misgivings have been entertained on the subject and a reaction of opinion has been setting in on all sides. Koch's bold denial of the transmissibility of bovine tubercle to man, based on the negative evidence of his failure to infect cattle with the human disease, was far from commanding general assent, not only from being wholly inconsistent with the results obtained by others, but from the fact that all he had succeeded in proving was the greater virulence of bovine tubercle in relation to rodents, carnivora, and monkeys, and if to them presumably to man himself; he had indeed proved too much. But the statistics of tuberculosis in childhood, for it is on the incidence of the disease in the age period in which milk constitutes the main article of food that the late Sir Richard Thorne laid stress, have within recent years been the subject of considerable discussion. He assumed that "tabes mesenterica" was in all or nearly all instances an obsolescent synonym for mesenteric tubercle. Many, however, maintain that as a cloak for ignorance or as a euphemism it covers a heterogeneous multitude of wasting diseases of nutrition, including even congenital syphilis, the cases of tuberculosis forming a negligible quantity. It is urged not only in this country but on the continent, where a fallacy in our nomenclature of diseases can have no influence, that the experience of the post-mortem rooms in children's hospitals gives no support to the notion that the milk of tuberculous cows can be held accountable for any appreciable amount of infantile tuberculosis, for tuberculous deposits in the mesenteric and intestinal glands appear, as in adults, to be almost always secondary to others in the lungs or pleura, and that the abdominal form is extremely rare as a primary disease. The obvious rejoinder is that when the two coexist it is quite impossible to decide which was the first in order of time, and that the course of infection in tuberculous meningitis is *viâ* the thoracic duct, the entrance of the bacilli having been effected per os. The whole question has been under discussion in the section of pediatrics of the German Association of Naturalists and Physicians at Carlsbad; the statement of Schlossmann that in Germany, at any rate, milk infection played but an insignificant part in infantile tuberculosis was accepted well-nigh unanimously. At the meeting held at Cassel in September last Ganghofner of Prague reopened the discussion on the report of Heller of Kiel who stated that among 714 children dying from diphtheria in the period 1873–94 tubercle was found in one organ or another in 140, or 19·6 per cent., and in 53 of these the glands of the alimentary canal were affected primarily, these being 37·1 per cent of the tuberculous cases, and in 33 of the 53 the mesenteric glands were alone affected, even the intestine itself remaining free.

The conclusions of Councilman, Mallory, and Pearce of Boston, U.S.A., drawn from the examination of 220 cases of diphtheria, agreed in the main with those of Heller, but Biedert, Baginsky, Hansemann, Virchow, Benda, and in short every other observer in Germany had, said Ganghofner, arrived at a very different opinion, Baginsky's figures, for instance, having been 144 cases of tuberculosis among 806 of fatal diphtheria, or 17·8 per cent., against Heller's 19·6 per cent., but only six, or 4·1 per cent., of the tuberculous cases having apparently been infected through the alimentary canal. Ganghofner, following in every detail, to the mode of examining the viscera, the methods of Heller, found among 972 cases dying from scarlet fever, diphtheria, measles, or small-pox evidence of tubercle in 252, or 25·9 per cent. In 179, or 71 per cent., of these the peribronchial lymph glands or the lungs or both were involved, and in 51, or 20·2 per cent., the bowels or mesenteric glands were so too, but in four cases only (two of measles and two of scarlet fever) was it limited to these. While Councilman and his colleagues at Boston, though dealing with but one-third of the material, arrived at results (37·8 per cent. of abdominal cases among those in which tubercle was present) almost identical with those of Heller at Kiel (37·1 per cent.), Baginsky at Berlin found the percentage of the total and of the abdominal cases of tubercle among children dying from infectious fever about one-tenth of the above, and Chiari in the course of seven months failed to find one in which the disease was restricted to the bowel or its vicinity. Hueppe has, however, suggested, and Penzoldt has proved, that in the act of swallowing the bacilli in milk may lodge in the tonsils, and setting up tuberculosis of the bronchial and tracheal glands simulate infection through the respiratory channels. Max Wolff, and more recently Weleminsky, feeding rabbits with tuberculous material induced pulmonary disease only, and the same results were obtained by Ravenel and by A. Hand of Philadelphia with apes, the intestines invariably escaping. It would appear, therefore, that the localisation of the lesions affords little, if any, clue to the mode of access of the infection, that ingestion no less than inhalation may lead to pulmonary and bronchial tuberculosis, while a primary pulmonary lesion may soon be put into the shade by the more extensive abdominal disease set up by self-infection through swallowing the sputa. In these circumstances the sole resource seems to be, as Biedert declared, the experimental feeding of large populations with different quantities of tuberculous milk. The conditions for this inquiry Biedert found almost ready to his hand in Bohemia where the mortality from every form of tuberculosis in the 85 districts, excluding Prague (where the influx of patients to the hospitals and the importation of foreign cattle would deprive the calculations of all value), ranged between 21·2 and 58·3 per 10,000 inhabitants and the percentage of tuberculous udders reported from the slaughter-houses from 0·03 to 1·8 But so far from there being any correspondence between the two the ratio was rather the reverse, and that for obvious reasons. Many districts are purely agricultural or forest, while others are densely peopled, the seats of industries and mining; and the incidence of tuberculosis varied directly as the density of the population, and in the urban districts the dairy farms were under better control. To this there was but one exception—viz., Gablonz, where both figures were high, the population being industrial and slaughtered cattle largely imported from Galicia. Ganghofner forbore to extend the like inquiry to Germany, being deterred by the extraordinary disproportion of tuberculous carcasses reported in the different states—e.g., 15·2 per cent. in Prussia, 29·39 per cent. in Saxony, and 6·3 per cent. in Bavaria—for which Ostertag of *Stuttgart accounts by admitting that in southern Germany* only the most pronounced cases were notified, whereas Biedert was satisfied as to the general uniformity of the practice in Bohemia. But before attaching great weight to the Bohemian figures it would be necessary to know something more as to the methods as regards death certification in the several parts of the country, and as to the death-rates from tuberculosis in the several age groups Similarly information would be desirable as to the methods of nursing in the several districts; whether, for instance, suckling or artificial feeding obtained, and whether in the latter case the custom of boiling the milk prevailed It would seem extremely probable that where overcrowding and poverty were present the effects of tuberculous milk, even if considerable, would be overshadowed. But on Behring's thesis infection by milk would exert its influence indirectly at every age period.

THE ACTION OF ANÆSTHETICS ON PLANTS.

THE close similarity in composition and properties of animal and vegetable protoplasm is brought into strong relief by the extremely interesting and curious investigations that have been recently made on the action of the vapours of ether and chloroform in promoting the process of inflorescence in plants or, in other words, in forcing them to flower at an earlier period than is natural to them. The production of early blooms in the lilac, the lily of the valley, the deutzia, and the azalea is a large and important industry in the early spring and for any grower to obtain well-developed flowers a week or two in advance of his brother horticulturists, especially if it can be accomplished at little cost, means large receipts and in addition the satisfaction of successful rivalry. Many years ago Claude Bernard, desirous of recording the phenomena common to animal and plant life, submitted both to the action of anæsthetics. He placed a specimen of the sensitive plant under a bell glass with a small sponge dipped in ether and found that after the lapse of a few minutes the expanded leaves became insensible and ceased to close when touched. This experiment has been the parent of much research of late years and the results obtained have been summed up by M. Emile Lemoine, a fellow of the Horticultural Society, and have been published in the last number (October, 1903) of the journal of that society. The next step was taken by Dr. W Johannsen of Copenhagen who, noticing that many plants push forth their buds after a period of repose such as occurs during the winter months or even in unfavourable seasons during the summer, conceived the idea that by inducing such a condition of rest by means of anæsthetics the plants would be, as it were, renovated and stimulated and rendered capable of developing their buds with greater vigour. Acting on this principle Dr. Johannsen was able to show at a meeting of the Copenhagen Academy of Sciences lilac blossoms forced by etherisation. The value of the proceeding was quickly recognised by horticulturists in Germany, France, and England, and these experimenters all proved in accord in regard to the remarkable power that the vapours of ether and chloroform have in promoting the formation of the inflorescence of plants. Lilacs, and especially the variety named Charles X. which is notably a difficult one to force, lilies of the valley, azaleas, and deutzias were subjected to the vapour of ether and timulant effects on the production not only of flowers but of leaf-buds and leaves were observed. M. Leblanc reported to the Société Centrale d'Horticulture de Nancy that his experiments with chloroform had been quite successful. On Feb. 19th last he chloroformed some plants of azalea mollis, giving them about half the quantity he would have used had it been ether and exposing them to the action of the vapour for about 48 hours. They were at once removed to a greenhouse at a temperature of 65°F. From March 5th the flowers began to expand a little and attained about to their full dimensions on the 8th, whereas plants grown for comparison were not expanded until

March 21st. The chambers in which the vapours are set free should be of large size and to prevent their escape should be absolutely air tight and all manipulation must be executed in the daytime since the approximation of a light if air has gained access to the interior is liable to be followed by violent explosion which may occasion great destruction of property and possibly loss of life. The quantity of ether employed to air was about 30 or 40 grammes of pure sulphuric ether boiling at 95° F. to 100 cubic litres of air and the duration of exposure one or sometimes two periods of 48 hours. The economy of fuel effected by this method of forcing, which can be done at either a high or a low temperature, is considerable and covers the cost of etherification.

RADIUM AT BATH.

AFTER the discovery of Sir William Ramsay that radium slowly evolves helion, it is not surprising that traces of radium should be found in the deposits of waters which evolve small quantities of that gas. Professor Dewar some time ago employed the gases from the King's Bath at Bath as a source of helion for experimental purposes. The Hon. R. J. Strutt, son of Lord Rayleigh, now reports that the deposits at Bath contain radium in detectable amount but the proportion is very small, though probably radium would be found in larger quantities at a great depth where helion is set free. Can the healing properties of the waters have anything to do with radio-activity?

PERITONITIS IN SCARLET FEVER.

IN the *Boston Medical and Surgical Journal* of Dec. 10th, 1903, Dr. J. H. McCollom and Dr. J. B. Blake have described two cases of a rare complication of scarlet fever—namely, general peritonitis. This complication is not mentioned in most of the text-books, including Allbutt's "System of Medicine." The cases now described were the only examples of it in 8000 cases of scarlet fever admitted to the Boston City Hospital. The first case occurred in a boy, aged five years, who was admitted on April 10th, 1900, with diphtheria. Two days later the skin became red and on the following day the diagnosis of scarlet fever was obvious. On the twenty-third day after admission the patient complained of abdominal pain and vomited but on examination nothing to explain it could be found. The urine became slightly albuminous and the vomiting, tenderness, and rigidity of the abdomen continued. Ten days later the umbilicus began to protrude and the area around it was red, swollen, and painful and the abdomen was distended and dull in the flanks. 43 days after admission paracentesis yielded 21 ounces of pus which showed on culture the streptococcus pyogenes. On the next day the umbilicus ruptured and for several days fluid leaked from it. On May 31st the thorax was aspirated in the seventh space and a few drachms of pus were withdrawn; the right ear was discharging slightly. Recovery followed. In the second case a man, aged 31 years, was admitted on April 22nd, 1903, on the seventh day of an attack of scarlet fever with a brilliant eruption and a systolic apical murmur. 13 days later there was a trace of albumin in the urine and he was slightly nauseated. On the following day there was abdominal pain. On May 9th there were abdominal tenderness and suppression of urine. Abdominal distension and rigidity rapidly developed. The legs were drawn up and the face became pinched. The abdomen was opened and a free discharge of thin pus, followed by a curd-like substance, took place. The intestines were red and congested. The peritoneal cavity was flushed with saline solution and drained with gauze wicks. The patient rallied but the suppression of urine continued and the vomiting increased. Death took place 25 hours after operation. A culture from the pus showed the streptococcus. At the necropsy a layer of fibrin was found on the diaphragm, the spleen, the liver, and both pleuræ. There were also acute nephritis and vegetative endocarditis. In both cases the peritonitis occurred late and apparently was due to secondary streptococcic infection which was part of a more general infection.

A PURE MALT WHISKY BILL.

WE understand from a very authoritative source that a pure malt whisky Bill is to be introduced into Parliament in the approaching session. We have for some time taken special pains to point out the urgent need there is for dealing with the practice of substitution which exists to an appalling extent in the spirit trade. We have vigorously maintained that the State should regard it as a fraudulent act to sell grain spirit as genuine malt whisky or genuine brandy, and that legislation should be adopted which shall require in the case of all spirits sold for consumption a label placed on the bottle containing a statement upon it accurately describing the nature of the contents It is not only a question of fraud that is concerned but a question also of injury to health We should be very gratified if some measure of control on the lines indicated were adopted, particularly as we feel that the inquiries instituted by THE LANCET Special Analytical Commission on Brandy opened the eyes of our readers and, through them, of the public to the blending tricks of the spirit trade. (It is interesting to note that according to the dictionary the word "blend" is allied to "blind").

THE BRITISH OPHTHALMIC HOSPITAL AT JERUSALEM.

Their Majesties the King and Queen are giving their patronage to an entertainment which is being arranged for the forthcoming season at His Majesty's Theatre in aid of the British Ophthalmic Hospital at Jerusalem. The entertainment will consist of historical tableaux and musical and dramatic performances by leaders in the operatic and theatrical world. Our readers do not require to be reminded of the terrible effects of ophthalmia in the East. They leave a lasting impression upon all travellers and represent an amount of suffering that is practically incalculable. With the object of relieving this form of suffering the institution known as the British Ophthalmic Hospital, which is the only one of its kind in the East, was started some 21 years ago as an out-patient dispensary within the walls of Jerusalem, and since that time has made much progress, relieving thousands of poor sufferers not only in the neighbourhood of Jerusalem, but along all the coasts of the Holy Land and in districts and countries still more distant. It has been found necessary from time to time to enlarge the size and to extend the sphere of usefulness of the institution till at the present moment there exists a well-built hospital standing in its own grounds of six acres on the Bethlehem-road with wards containing 50 beds under the supervision of two experienced resident English surgeons. But this extension necessarily means increased cost and the annual subscriptions have been totally inadequate to meet current expenses. In order that the 50 beds may be always available a sum of £2000 annually is necessary, but towards this there is only a small endowment fund bringing in less than £50 a year, while the annual subscriptions amount to the paltry sum of £300 a year. Like the hospitals in this country the British Ophthalmic Hospital opens its doors to all of whatever race or creed and it is non-proselytising and non-political. On the other hand, it is organised by a great Christian order of chivalry, the Order of the Hospital of St. John of Jerusalem in England, and is supported mainly by Christian charity. The statistics for 1902, when only 16 beds were available, show that there were 674 in-patients admitted, 6062 new out-patients, and a total attendance of out-patients of 19,196. The number of operations performed was 1271 and anæsthetics were administered 680 times. An institution standing by itself as this one does and performing such excellent service to the sick poor ought not to be compelled to plead for funds and we hope that the charitable public will when the facts become known respond liberally. The deprivation of sight is one of the saddest calamities with which the human body can be afflicted and a charity which administers to the defects of the physical organ of sight must be worthy of universal sympathy and help; nor should we forget that the healing of the blind formed part of the ministrations of a Great Physician and Master whose birth some 1900 years ago in the land where the British Ophthalmic Hospital is situated we have but recently celebrated. Subscriptions should be sent to the honorary secretary of the British Ophthalmic Hospital, The Chancery, St. John's Gate, Clerkenwell, London, E C.

ANTIDIPSO.

IN reference to analyses made by Dr. R. Hutchison at the London Hospital and by ourselves of the specific for drunkenness called "Antidipso," we published in THE LANCET of Dec. 19th, 1903, p. 1742, our estimate of the value of the preparation. We received thereupon a visit from Mr. A. L. Pointing who brought the originals with him of certain testimonials which he had previously forwarded to us. He has since sent us the following letter:—

The English Illustrated Magazine,
Bloomsbury Mansion, 24 and 25, Hart-street,
London, W.C., 2nd January, 1904.

Manager, THE LANCET, 423, Strand, W.C.

re Antidipso and the Ward Chemical Co.

DEAR SIR,—Referring to my interview with you yesterday when I placed before you evidence, in the way of original testimonials, bearing out our claim that Antidipso cures drunkenness, the letters you had before you showed that the cure was equally effective where the powders had been administered without the knowledge of the patient as it was when taken with the patient's knowledge.

You read letters from patients themselves blessing the day that they took Antidipso; you had letters from mothers, wives, and sisters thanking us for putting within their reach the means of curing their brothers, husbands, and fathers of the craving for drink.

All this data fully warrants the claim we make for this specific and we feel sure that you will do us the justice of making known to your readers the result of the interview and the knowledge that you now have that our specific, Antidipso, does what is claimed for it, viz., it cures the craving for alcohol.

I trust that I shall see this reference made by you in your next issue.

Yours faithfully,
ENGLISH ILLUSTRATED MAGAZINE,
A. L. POINTING, Director.

We have no objection whatever to publishing Mr. Pointing's letter as he desires. His statement that "this data fully warrants the claim we make for this specific" is not borne out. We do not believe that "Antidipso" cures the craving for alcohol and no amount of testimonials from drunkards, or the friends of drunkards, even if we had tested their accuracy, could possibly be accepted as a proof of what is claimed.

PULMONARY TUBERCULOSIS IN LEWIS.

ALTHOUGH pulmonary tuberculosis may be said to be one of the diseases affecting mankind generally, yet in some parts of the world it is certainly rare. For instance, it is said to be very uncommon in the Faroe Islands, in the Hebrides, and in Iceland. We have received a communication from Dr. C. M. Macrae, medical officer of health of Lewis district, which is of interest in reference to the geographical distribution of this disease. He draws our attention to a passage in Miss Goodrich-Freer's book "The Outer Isles." This writer quotes from an older work, Smith's "Lewisiana," and endorses the statement as a present fact that "tubercular consumption is unknown in Lewis." Dr. Macrae says, "For the sake of truth and the best interests of Lewis men this assertion has to be not only disputed but very seriously denied." He goes on to remark that a century ago, when this remote "outer isle" was more isolated from foreign intercourse and outside influences and diseases, the island may have been justly credited with partial, if not total, immunity from pulmonary tuberculosis. This statement is corroborated by the observations of Dr. D. Christison recorded in the Transactions of the Society of Scientific Associations in 1863; and Dr. Morgan, writing in 1855,[1] suggested that the immunity was due to peat smoke. Dr. Macrae says, however, that "this semi-Madeira character of a blessed exemption from a malady so death-dealing can no longer be maintained, much less boasted of." He states that the victims of the disease in Lewis number from 46 to 60 annually and are yearly on the increase. The insular authorities, he adds, are resolved to take such steps as may prove efficient in securing such remedial means as have proved successful elsewhere in checking the spread of the disease. This marked change in the local incidence of the disease is interesting as demonstrating the communicability of the disease by means of intercourse between an insular community and the general population.

THE SKI.

SKIS, like snow-shoes, are intended to facilitate progression over snow but whereas with the latter laborious tramping is essential with the former an easy gliding motion like that of a skater on ice can be maintained with comparatively little exertion when the snow is sufficiently deep and smooth. The chief objection to snow-shoes is the width of the tread which compels the wearer, especially if of short stature, to straddle to an uncomfortable extent. The ski, on the contrary, is quite narrow and yet owing to its great length the superficies it opposes to the snow is considerably larger than that of its racket-shaped rival. A ski consists of a slender strip of hard elastic wood, generally ash, about eight or nine feet long but only a little wider than the sole of the wearer's foot and nowhere much more than one inch in thickness. Anteriorly it tapers to a point which is curved upwards, the posterior end being similarly bent but to a much slighter extent. An expert on skis can travel at the rate of five or six miles an hour or more on flat ground, but down hill there is scarcely any limit to the speed which he may attain. 20 or 25 miles an hour is not considered an excessive rate under favourable conditions. As will readily be imagined, rapid movement on a yielding surface beneath which unseen, or only faintly indicated, obstacles may exist cannot be free from danger. In Norway where skis are universally used, even by children going to school and by postmen on their rounds, accidents are said to be extremely rare, if not altogether unknown, but elsewhere unfortunately the record is less favourable. No doubt the great depth of the snow throughout the Scandinavian peninsula is sufficient to account for the immunity. The deeper the snow the less danger there is of unseen obstacles and even if falls should occur they are little likely to be attended by injury when the hard surface is abundantly covered. A fatal ski accident which occurred in the French Alps was reported in the *Archives de Médecine Militaire* for August, 1903, by Surgeon-Major C. Legrand. A soldier belonging to the 30th Chasseurs was taking part in ski drill with his company near Barcelonnette when passing over a concealed irrigation channel at a high rate of speed he stumbled and nearly fell. He was going down hill at the time and in the endeavour to save himself contrived to knock his iron-pointed staff against one of his skis. It swung round base downwards and lodged in the snow, whereupon the sharp end struck him under the right jaw bone, inflicting a punctured wound. Immediately a jet of arterial blood spouted but his comrades were able to control the flow by digital pressure on the wound. At the regimental hospital the submental artery was ligatured and at once all hæmorrhage ceased, but on recovery from the chloroform it was found that left hemiplegia had occurred. That evening there was slight oozing of blood from the wound. Death from coma took place about 48 hours fter the accident. At the post-mortem examination the ommon carotid artery was found to have been wounded s well as the submental. The carotid wound was horiontal, only about one-third of the vessel remaining intact

MISTLETOE.

IT is difficult to see by what exact process of reasoning mistletoe (*Viscum album*) has come to be regarded as oisonous by the vulgar. Botany books describe the fruit s "inferior" but succulent and we know that birds, especially the mistle-thrush, eat it and convey the undigested eed to the trunks of trees to which its viscous coating nables it to adhere. Writers from Paracelsus down to quite recent times have been loud in their praises of mistletoe as a cure for epilepsy and as lately as 1881 Dr. R Park, writing in the *Practitioner*, describes a mining district in the Forest of Dean where heart troubles were habitually treated with a certain tincture of mistletoe, which was handed on to him among medicine bottles found in a rural surgery. This proved a good substitute for digitalis. At the beginning of the eighteenth century Colbatch published a work upon mistletoe which ran into many editions. He describes a drug made from the plant as "a most wonderful specific remedy" for convulsions and as late as 1806, if not later, the same drug is prescribed most confidently by a certain Dr. Henry Frazer in cases of epileptic seizure. Going back to the days of Pliny we find that philosopher describing the *Viscum album* as an antidote to poison and a remedy for sterility. His, too, is the classic description of the plucking of the mistletoe by the Druids. At a later period, but still long before medicine had arrived even at the "signaturist" stage, mistletoe is found playing a great part in the Volu pa and other Scandinavian sagas. It was with a sprig of the plant, or an arrow made of the stalk of the plant, that the blind and somewhat dull-witted god Hodur was induced by Loki, the evil principle, to have his fling, in a literal sense, at Balder, the Daylight or good principle. Myth represents Balder as being killed outright by the mistletoe, a little plant growing on the eastward slopes of Asgard, and the sole thing among minerals, plants, and poisons, as well as among gods and men, that had not promised Freya to be harmless if used against her son Balder. Within this myth of the German forests there are doubtless other myths, but it is to this ne, perhaps, that the mistletoe owes its character as a poisoner, a remedy in cases of "soul disease"—for it was thus that epilepsy was regarded—and as a presider over chartered liberties between the sexes now symbolised by kissing.

GANGRENE OF THE KIDNEY.

IN the *Australasian Medical Gazette* for November, 1903, r. R. E Weigall has published the following case of the re condition of gangrene of the kidney. A married woman, ged 23 years, was seized with sickening pain in the region the right kidney which extended down the right leg and as followed after an hour by hæmaturia. While at rest in d she was free from pain and had a temperature of 100° F. palpation the right kidney was very tender and any ovement caused pain. On the next day the urine was ood-stained but there was no evidence of fresh hæmorage. The temperature was normal, the kidney was tender, and pain occurred on any movement. In the evening, 28 hours after the onset, there was a severe rigor, the temperature rose to 104·6°, and the urine was scanty. On the following day the urine which had been passed in 24 hours amounted to only 26 ounces but was normal in character. On the fifth day 23 ounces of urine were passed and the kidney was apparently functionless. It could be grasped and manipulated without pain. The patient was rapidly becoming worse. The temperature ranged between 103° and 104°. The symptoms included a coated tongue, vomiting, and a pulse of from 140 to 160 per minute. Gangrenous kidney was diagnosed. Although the patient appeared to be moribund an operation was performed. A large loose gangrenous kidney, which was completely twisted on its axis, was exposed. The pelvis was quite green. The kidney was removed. From the hour of operation the patient began to rally. Saline enemata were given. In four days the daily secretion of urine reached 52 ounces. The immediate cause of the twisting of the kidney appeared to be that when the patient was watering her garden one of her children jumped straddle-legged on to her hips and struck his knee in the region of the right kidney which was already loose

WARDROP'S OPERATION FOR ANEURYSM.

THE brilliant success which followed Hunter's operation for aneurysm by ligation of the artery on the proximal side of, and at a distance from, the sac led to its employment for most of the larger arteries of the body, but there were some aneurysms which were not amenable to this mode of treatment because it was impossible to apply a ligature on the proximal side of the aneurysmal sac The most important member of this category is the innominate artery. The vessel itself is short, only about one and a half inches in length, so that the aneurysm would need to be close to the bifurcation and very small in size to allow of the application of a ligature on the brachiocephalic trunk between the sac and the aorta Such conditions never occur in practice and, therefore, for the treatment of an innominate aneurysm proximal ligation is impossible. This was the position towards the close of the first quarter of the nineteenth century when James Wardrop suggested that distal ligation would probably have an effect identical with that produced by the application of a ligature on the proximal side, and his aim in making this suggestion was to arrest completely the flow of blood through the sac so that coagulation could occur, though the hydrostatic pressure would not be lessened, at all events at first. In the case, however, of an aneurysm of the innominate it must be rarely, indeed, that it is possible to apply a distal ligature to the vessel itself and therefore Wardrop made the suggestion that the branches of the innominate, the carotid and the subclavian arteries, should be tied instead. The difficulties in ligating the first or second part of the subclavian artery are very great and therefore Wardrop advocated tying the third part Inasmuch, however, as many branches come off from the subclavian in the first and second parts ligation of the third part cannot, even when combined with occlusion of the carotid artery, lead to a complete stasis in the blood flow through an innominate aneurysm, but experience has shown that it does at least modify the blood stream to such an extent as to promote the deposition of coagulum in the aneurysm. It will be seen that Wardrop suggested the ligation of *both* branches of the innominate artery but curiously nearly every text-book on surgery describes Wardrop's operation as ligation of one only of the branches. In "Looking Back" in THE LANCET of Jan. 2nd, 1904, p 48, we have reprinted a review of a paper by Wardrop describing a case of carotid aneurysm in which he had successfully applied a distal ligature to the artery. It is perhaps the situation best suited for a distal ligature when an aneurysm involves the carotid artery near its origin. This operation was first performed on the carotid artery by Wardrop, though it is named after Brasdor who treated a femoral aneurysm by this method in 1799.

THE UNIVERSITY OF LONDON: INSTITUTE OF MEDICAL SCIENCES.

WE understand that towards the fund being raised by the Senate of the University of London for the proposed Institute of Medical Sciences, Mr. H. T. Butlin, the dean of the Faculty of Medicine, has contributed £1000; Sir William Church, Bart., K.C.B., President of the Royal College of Physicians of London, £100; and Mr. J. Tweedy, President of the Royal College of Surgeons of England, £100.

ANOTHER FATAL ACCIDENT ON SCAFELL.

THREE months only have passed since we recorded a fatal accident on Scafell.[1] Another fatal accident took place near the scene of the last disaster on Dec. 26th when a party of climbers attempted the ascent of Scafell, avoiding the dangerous route taken by the ill-fated party in September of last year by climbing the way of Steep Ghyll. On their return from the summit of Scafell two of the party attempted the descent of Deep Ghyll, which is generally a rock climb, but on this occasion the ghyll was filled with snow and the climber, Mr. Goodall, who subsequently lost his life, wishing to gain further practice in glissading, took the lead. He safely descended the ghyll, passing over the screes and the lower edge when he stopped suddenly, then to the horror of the other climber he began to slide down the slope, unable to control himself, and finally disappeared from view. His body in falling struck the rocks on Lord's Rake at the base of Deep Ghyll and death seems to have been instantaneous. It is a somewhat sad coincidence that the deceased was a journalist who supplied several of the accounts relating to the last fatal accident. It is probable that no amount of ordinary foresight would in this case have prevented the accident, but as we understand that the victim insisted on taking the lead it is quite possible that his own confidence may have contributed to the accident. In such an exhilarating pastime as mountain climbing the dangers by which it is attended may easily be forgotten and the need for caution cannot be too often reiterated. This is the more emphasised by the fact that Mr. Goodall is said to have been an experienced climber.

A PRIZE in clinical medicine has recently been founded at Charing Cross Hospital by the old students and friends to commemorate the connexion of Dr. T. H. Green with the hospital and medical school for the long period of 34 years. The prize is open to all unqualified Charing Cross students who have finished their preliminary work and have prosecuted their clinical studies for not less than one year at the hospital. It will be given for the best work done upon some special subject involving simple clinical observation in the wards or clinical laboratory and on the result of a practical examination on cases in the wards. The subjects of research may be chosen by the candidates themselves but they must be submitted to the examiners for their approval.

THE medical officer of health of the Cape Colony states that for the week ending Dec. 12th, 1903, no case of bubonic plague in a human being was reported from any place in the colony. Plague-infected rats were found at Port Elizabeth, East London, Queenstown and Knysna, but of 631 examined in the Cape Town and Harbour Board area was affected with plague. As regards the Mauritiu telegram from the Acting Governor received at the Colo Office on Dec. 26th states that for the week ending Dec. there were 62 cases of bubonic plague and 41 deaths the disease.

THE annual course of lectures at the Hospital for sumption and Diseases of the Chest, Brompton, will opened by Sir Richard Douglas Powell on Wednes Jan. 27th, when he will take as his subject Foreign Bodie the Bronchi. The lectures for 1904 will be delivered as at 4 P.M. on Wednesday afternoons and will be fre qualified practitioners and to students of medicine.

THE opening clinical lecture of the spring session of North-East London Post-Graduate College will be give the Tottenham Hospital by Dr. T. Gilbart Smith, physi to the London Hospital, on Thursday, Jan. 14th, at 4.30 The subject announced is Certain Points in the Diagnos Fluid in the Chest and all medical practitioners are invite

AT the National Hospital for the Paralysed and Epile on Tuesday, Jan. 12th, Dr. J. A. Ormerod will lecture Friedreich's Ataxy and on Friday, Jan. 15th, Dr. C. Beevor will lecture on Muscular Atrophy.

Looking Back.

FROM

THE LANCET, *SATURDAY*, JAN. 7, 18

I believe that much mischief has been done by the application of bandages to diseased parts, with a view stimulate the absorbents," without that attention to the lower part of the limb, which is essential to the pati safety. It has not been proved that we possess any di power or control over the absorbents; whilst the powe limiting or controlling deposition is evident and dem strable. You are no doubt aware that every part of living body (except the hair, nails, and teeth) is un going perpetual change, differing in degree according to various textures, but extending even to the solid parts may be proved even in the bones. Now to effect this two opposite functions are necessary, the one the bringi deposition of new matter, the other the removing or away that which has become useless; the latter of functions is termed absorption; now so long as the tion and absorption are equal to each other, the although undergoing continual change, will neither nor diminish; but if the deposition exceed the accumulation must result; and if the absorption the deposition of new material, diminution or wasting the part must ensue. Hence, therefore, we may trace wasting of limbs under the use of bandages, (often empl by beggars and others who simulate diseases) and the beneficial effects of diminishing the swellings and ments which have been produced by disease, more to the compression of the bloodvessels, which diminishes quantity of blood circulating within them, without to any other power, supposing the absorption to continue its usual rate. The more you investigate this subject more demonstrable it will appear. The pathology of swelling of the lower extremity sometimes occurring childbirth, termed *phlegmasia dolens*, has shown that return of the blood has been obstructed in the vein, the obstruction not extending to the artery, the blood continued to be propelled into the limb, and the more or serous portion of it forced into the surrounding parts, ticularly the cellular structure. Now this swelling the actual obstruction to the circulation of the blood demonstrated, and Dr. D. D. Davis has the merit of been the first, in this country at least, to publish the ledge of this interesting fact; this swelling, I repeat, long been considered as a disease of the absorbent system, and many ingenious hypotheses had been framed to explain it; but their fallacy became obvious when demonstration afforded the light of truth.[1]

[1] THE LANCET, Sept. 26th, 1903, p. 896.

TRAINING OF, AND REGULATIONS FOR, MIDWIVES IN ITALY.

I.—TRAINING OF MIDWIVES.

THE importance of a careful education of midwives has long been recognised in Italy and their training made a special care of the State. In a country where, even more than in England, the bulk of obstetric practice is in the hands of the midwife and where social and climatic conditions probably favour the spread of infection to an unusual degree it was indeed most necessary for the welfare of the community that all the protection possible should be afforded to parturient women, especially of the lower and poorer classes, among whom the mortality from puerperal fever had been very high. Trustworthy statistics as to the death roll from this cause previously to the year 1887 are unfortunately not obtainable, but it is admitted to have been very heavy. From 1887 onwards, however, a separate record has been kept of such deaths and the total number for each year, together with the proportion it bore to every million of inhabitants, is given in the subjoined table, the last column of which shows also the deaths from causes incidental to pregnancy, parturition, and the puerperium other than puerperal fever:—

Year.	Total deaths from puerperal fever.	Rate per 1,000,000 inhabitants.	Total deaths from other diseases of pregnancy, parturition, and puerperium.	Rate per 1,000,000 inhabitants.
1887 ...	2504	85	4436	150
1888 ..	2451	83	4430	149
1889	2106	70	4003	134
1890.. ...	1662	56	2713	90
1891	1633	54	2445	81
1892	1530	50	2233	73
1893... ...	1774	58	2216	72
1894... ...	1604	52	2444	79
1895	1514	49	1893	61
1896	1292	41	2335	75
1897	1199	38	2143	63
1898	1214	38	2016	66
1899	1302	40	2270	71
1900... ...	1033	32	2001	62
1901... ...	994	30	1773	54
1902	1037	32	1746	53

One of the most potent factors contributing to the improvement noticeable in the later years as shown in this table has without doubt been the better equipment of the midwife for her responsible duties and the precautions taken by her as a result of her more careful training.

The education of the midwife was placed under the supervision of the Government in virtue of a law passed in 1876 for the institution of obstetric schools. According to this enactment such a school can be established in any city where a university or a medical school already exists, the necessary funds being provided by the Minister of Public Instruction in conjunction with the provincial or the communal authority, and the direction and the teaching being undertaken by the professor of obstetrics of the local university or medical school. It can also be established in any other city, but then one or other of the local authorities must bear the cost. The latter class of schools may be placed on the same footing as those connected with the universities by their fulfilling the requirements of the present law, for the purposes of which the kingdom is divided into university districts, each school of obstetrics falling under the jurisdiction of the university in the district of which it happens to be.

Every obstetric school is required to have in addition to the directing professor (who is nominated by the King) at least one doubly qualified medical assistant and one certificated midwife, both of whom are nominated by the Minister. According as the necessity may arise there may be added, on the advice of the directing professor, other qualified assistants and midwives who are also nominated by the Minister. Further, no obstetric school can be established except in connexion with a maternity hospital or a hospital containing at least 15 beds for maternity cases and in which in the course of a year the number of labours is not less than 120, taking the average of the last five years. The number of pupils must not exceed that of double the number of beds. There are intern pupils, who have their quarters and food in the school, and extern pupils, who live outside, but all are equally subject to the discipline of the school, the rules of which must have received the approval of the Minister of Public Instruction. To be admitted as a pupil the candidate must be healthy, free from physical imperfections which disfigure or unfit her for the work, and must have attained the age of 18 years and not passed that of 36. She must produce a certificate of good conduct from the municipality of the commune where she has lived for the last two years and of having been successfully vaccinated or of having had small-pox. In order to be admitted to the examinations for the midwife's diploma the candidate must have passed the entrance examination of the third elementary class or other equivalent test and have paid the matriculation and inscription fees. (The total fees for the curriculum, including that for the diploma, amount to 89 francs—£3 11*s*). Having fulfilled these requirements she is furnished with an inscription card upon which a report is written every two months as to the pupil's diligence, progress, and conduct. At the end of the second scholastic year the pupils who have passed the examination of the first year present to the rector of the university or to the directing professor of the school an application to be allowed to continue the practical course

As to the teaching itself it is partly theoretical, partly practical, the former being given in the form of lectures by the directing professor, the latter at the bedside of the patient The theoretical course lasts one year; the practical course commences simultaneously with the theoretical and lasts two years for extern pupils, whilst for intern pupils the second year's course is reduced by one third. There are two examinations, the first being held during the last ten days of the theoretical course, the second at the end of the practical course. The theoretical examination consists of two parts—a written and an oral, the former lasting not more than four hours, the latter half an hour. The examining commission (which consists of the directing professor of the school as president and two other members nominated by the university of the district on the advice of its medical faculty) decide by vote whether the candidate has passed or not and if the majority declare in her favour the individual members, each of whom disposes of five points, award three, four, or all of these according as the candidate has secured "simple approval," "distinction," or "eminence" respectively in the examination. In the case of a poor candidate who obtains "eminence" the matriculation and first year's fees are returned to her. In order to gain admission to the practical examination the candidate is required to present the history of two cases observed by her during the clinical course written by herself and signed by the directing professor. The examination is oral, lasts at least one hour, and is made to turn partly upon the two cases presented by the candidate and partly on the principal obstetric manipulations as practised on the phantom. Questions are also put regarding the diagnosis of pregnancy and obstetric explorations, on the method of assisting at labours, on the dangers and the precautions necessary in complicated cases, and upon the duties of midwives in the exercise of their profession. The votes of the commission are then taken as before and the successful candidates receive diplomas from the universities of their districts conferring upon them the right to practise.

Women who a [illegible] of this law

three years—i.e., from 1880 onwards—no one not holding the regular diploma has been allowed to practise as a midwife in Italy.

II.—REGULATIONS FOR MIDWIVES.

With that regard for detail which characterises Italian legislation in sanitary matters very precise instructions are contained in the Act of Parliament dealing with the duties of midwives practising in Italy, whether these exercise their profession independently as private individuals or whether they do so in the capacity of paid servants under the control of the communal authority. While exception may be taken to some of these directions, as, for instance, to that recommending the routine douching of the vagina by the midwife, which by many will be considered inadvisable, it will be seen that on the whole the rules given are excellent. That they were not without a favourable effect would seem to be borne out in a striking manner by the statistics already quoted, in which it will be observed that a remarkable reduction in the number of deaths from puerperal fever occurred in the first year after their introduction—namely, in 1890, a fall in the mortality having taken place in that year of 14 per million from that of the previous year, equal to a diminution of 20 per cent. The Act referred to was put in force on Feb. 23rd, 1890, and is termed "Special Regulations and Instructions for the Obstetric Practice of Midwives in the Communes of the Kingdom." Its provisions, which are worth quoting pretty fully, and which still remain unmodified by later legislative measures, are as follows:—

Article 1.—Every midwife must provide herself with a bag containing the means necessary for assisting at a natural labour and [illegible] in urgent cases. In this bag must be kept [illegible] which accompany the present regulations. [illegible] fe will attend with the greatest possible accuracy to the rules laid down in the instructions.

Article 3.—The midwife is obliged to call a doctor immediately any- [illegible] bour, or during the puerperium, [illegible] ken with a thermometer placed [illegible] (100·4° F.)

Article 4.—Should no doctor be procurable the midwife, as soon as the temperature taken as above rises at any period of the puerperium over 38·5° C. (101·3° F.), will notify the municipal authority of the fact in order that the necessary measures may be taken. In case she should fail to do so she will be punishable by fine.

Article 5.—The midwife is hereby prohibited from employing surgical instruments or practising manual operations on the fœtus in utero for which she is not authorised by her diploma, except in cases of exceptional urgency where it is not possible to procure medical aid in [illegible] midwife assumes the responsibility of [illegible] of this article is punishable by a fine

Article 6.—A midwife who has attended a woman affected by any infective puerperal process must abstain from the exercise of her profession for at least five days wherever it is possible to provide other help for obstetric cases. In any case the midwife must not approach another pregnant, parturient, or puerperal women without having had the written authorisation of the communal sanitary officer who will ascertain whether she has been subjected to a thorough and effectual disinfection according to the rules prescribed in the instructions accompanying the present regulations. Any contravention of this injunction is punishable by a fine of 500 francs (£20) and with imprisonment for from one to six months.

Article 7.—Every midwife must keep a register of the confinements she attends by order of the communal authority, recording each case as soon as possible after the termination of the labour.

Article 8.—In terms of the sanitary law midwives are entitled to have the medicines and antiseptics which they require for the poor whom they attend in labour supplied to them gratuitously by the commune or institution whose duty it is to provide gratuitous attendance for the parturient poor.

INSTRUCTIONS FOR MIDWIVES.

Article 1.—Every midwife called to assist a parturient woman must bring with her (*a*) a bag containing t[illegible] Irrigator to hold one litre, a rubber tub[illegible] to it, and two vaginal glass tubes; (2) [illegible] nail file; (3) an apron of white material, fr[illegible] sleeves, of such form and size as to cover the whole of the front part of the person; (4) a stethoscope; (5) a Centigrade maximum thermometer tested for accuracy; (6) a pair of scissors for cutting the cord; (7) a gum-elastic catheter for drawing off the urine and a gum-elastic sound. *b.* Materials for disinfection: (1) boric acid, 200 grammes (six and two-third ounces), divided into five equal powders, one of which is to be dissolved from time to time as required in a litre of hot water to serve for vaginal irrigation and for disinfecting the hands and instruments; (2) soap; and (3) carbolised cotton-wool or sublimate-wool for vaginal plugs.

Article 2.—The midwife on her arrival at the house of the patient will see that, as far as possible, the room in which the labour is to take place and every article required is perfectly clean and especially that the linen has been freshly washed. She must then (1) prepare two litres of the antiseptic solution in the way indicated in Article 1 (*b*); (2) pour a sufficient quantity of this solution in a basin and immerse in it for at least ten minutes the instruments used in the course of the labour—namely, the vaginal tubes, the catheter, and the scissors; (3) after having turned up the sleeves of her dress above the elbows wash her hands and forearms with soap and water for the space of at least five minutes, paying especial attention to cleaning the nails with scissors, file, and nail brush. She will then put on the apron and again wash the hands, this time with the antiseptic solution.

Article 3.—After these preparations the midwife may approach the patient and, if the case be not urgent, proceed to an external examin tion, endeavouring thus to ascertain the most important data regar ing the presentation and the conditions of health of the fœtus l means of palpation and auscultation. She will then wash the extern genitals and adjacent parts (the perineum and the upper part of t thighs), using first soap and boiled water and then repeating t ablution with the antiseptic lotion already prepared.

Article 4.—She will then prepare another litre of the antiseptic solu tion, pouring half of it into a clean basin for again washing the hand and then proceed without drying them to make the vaginal examina tion. The washing of the hands in the antiseptic solution is to b repeated each time in the further course of the labour that it i necessary to explore the vagina.

Article 5.—The vaginal examination must not be repeated oftene than is absolutely necessary, whilst on the other hand, auscultatio should be practised frequently, especially after the membranes hav ruptured. The midwife must place nothing in contact with th genitals except carbolised or sublimated cotton-wool, or pieces of line freshly washed and soaked in the antiseptic solution. She must neve use sponges. Not even to facilitate the labour should she let th fingers remain in the vagina and she must not anoint the nails wit greasy substances.

Article 6.—The labour having terminated the midwife is to examine the placenta and membranes attentively and in case they are incomplete to keep them for the inspection of the doctor. She will then practise a vaginal irrigation with the antiseptic lotion, remove the soiled linen from beneath the patient, directing it to be taken out of the room and finally see that the floor of the room is also thoroughly cleansed of all extraneous matter.

Article 7.—During the first eight days the midwife will visit the patient if possible twice daily taking her temperature each time and ascertaining the condition of the lochia and watching carefully the course of the puerperium.

Article 8.—During the first five days she must wash the external genitals carefully with the antiseptic solution and in cases of suspected lochia also wash out the vagina with the solution, calling in the doctor in terms of Article 3 of the regulations. Either the irrigator or pieces of freshly washed linen or antiseptic cotton-wool soaked in the antiseptic solution should be used for the washing. She should also see that the linen worn by the patient is always fresh from the wash when put on.

Article 9.—The eyelids and the parts around the eyes of the new born infant are to be washed by the midwife with the antiseptic solution and if any inflammation of the eyes should develop later the doctor should be called immediately, frequent use being meanwhile made of the boric lotion.

Article 10.—When any cases of puerperal fever break out in the locality where the midwife is practising or in the neighbourhood she must attend with the most scrupulous care to these regulations and instructions.

Article 11.—A midwife who has come in contact with a puerperal patient suspected to be suffering from puerperal fever or from uterine inflammation must in terms of Article 6 of the present regulations abstain from the exercise of her profession for five days. In case of absolute necessity this period may be shortened with the permission of the local medical officer, given in writing. During this time she will change her clothing and the linen she wore while with the patient and disinfect them by immersion for ten minutes in boiling water. Further she will repeatedly wash the hands and forearms with the antiseptic solution according to the rules laid down in Clause 3 of Article 2 of these instructions. In commun [illegible] the midwife will consign to the [illegible] wore when in attendance on the [illegible] they may be disinfected.

Article 12.—The instruments used by the midwife must be cleansed and disinfected every time they have been in use by immersing them in water brought to the boiling point and then allowing them to remain in the antiseptic solution. For gum-elastic instruments it will be sufficient to wash and to immerse them in the antiseptic solution

THE FEES OF MEDICAL WITNESSES.

THE report issued by the departmental [illegible] appointed by the Home Secretary to inquire into the allow ances made to prosecutors and witnesses in criminal ceedings was discussed in THE LANCET of July 18th, 1903, p. 182. The regulations since made by Mr. Akers-Doug as the result of that report came into force on Dec. 28th, 1903, and apply to all criminal prosecutions—that is, petty sessions as well as to quarter sessions and assizes. far as they affect medical men giving professional evidence they are as follows: "There may be allowed, for atte to give evidence in the town or place where the residcs or practises, if the witness attends to give in one case only, not more than one guinea per diem; if witness gives evidence on the same day in two or m separate and distinct cases not more than two guineas. attending to give evidence elsewhere than in any town place where the witness resides or practises, whether in or more cases, not more than two guineas per diem. In regulation 'town' means municipal borough or urban trict and '*place*' means the area within a radius of miles from the court at which the witness attends to evidence. There may be allowed to expert witnesses allowances for attending to give expert evidence as the c may consider reasonable, including, where necessary, an allowance for qualifying to give evidence."

The following general regulation applies to all witnesses and so affects medical men: "No full-day allowance shall be paid unless the witness is necessarily detained away from his home or place of business or employment for at least our hours for the purpose of giving evidence. If the time during which the witness is necessarily detained away from his home, or place of business, or employment, be less than our hours, he shall receive not more than one half of the allowance which he would have received had he been detained for the full day."

The regulations quoted are not characterised by perfect lucidity and it is not impossible that disputes may arise as to their construction or that different practices may prevail where costs are taxed by different officials. It seems clear, however, that the medical witness in one case at petty sessions should now receive a guinea where he resides or practises within three miles of the court, an additional guinea if he resides beyond that distance, and not more than half these fees should he be detained for less than four hours. This latter condition is very objectionable in that the medical witness never knows beforehand for how long he will be wanted and his detention for three and three-quarter hours must necessarily dislocate his work for the whole day in addition to the necessity which he may feel for making provision for a whole day's absence. This is the case at assizes and at quarter sessions more than when the case is to be heard at petty sessions. Beyond this the new regulation is a gain to the medical profession so far as petty sessions are concerned, as the maximum fees before were half a guinea if the witness resided within two miles of the court and a guinea beyond that distance. We believe that at some petty sessional courts no fees have been paid to medical witnesses. This condition should cease now that fresh regulations have been issued clearly sanctioning their payment in all cases. The regulation says that "not more than" the sums named should be allowed but medical men will resist any attempt to curtail fees which in most cases will be insufficient to recoup them

It seems clear also from the regulations quoted that the medical witness who proceeds in due course to give at assizes or at quarter sessions evidence relating to one indictable offence will receive a guinea per day while waiting and a guinea or half a guinea, according to circumstances, on the day on which he gives evidence and that he will receive two guineas instead of one when he resides or practises more than three miles from the court. What is to happen, however, when he attends a court to give evidence in two or more distinct cases is not quite so plain but apparently he will be allowed only one guinea per day until all the cases in which he appears are concluded, with the exception that if by chance two or more of them are heard upon the same day he will then be paid two guineas. The rule as to residence or practice at a distance will help him to the extent that he may receive two guineas a day instead of one, but that sum will not be exceeded for any day in however many cases he may have to give evidence. This regulation is a gain to the medical profession in that under the old system of payment it was not possible for a medical witness to receive more than a guinea for any one day, in however many cases he was heard or from whatever distance he came. It is insufficient and unjust in that it still leaves the witness who has to give evidence in more than one case without extra remuneration unless a purely fortuitous incident happens—that is to say, unless two of his cases are tried upon the same day. He has the anxiety inseparable from giving evidence [illegible] where the liberty, perhaps the life, [illegible] t stake, imposed upon him owing to [illegible] aber of a certain learned profession. That anxiety is multiplied by whatever number of cases he may be concerned in and yet, except on the happening of the contingency mentioned, he is still to receive no addition to an already inadequate compensation. On the other hand, the fund from which the fees which should be his are drawn is to profit to the extent sometimes of many guineas wherever chance directs that the same medical witness shall appear in more than one trial instead of different medical men being called in each.

With regard to travelling allowances, the new regulations applicable to all witnesses are as follows: "There may be allowed to witnesses attending court to give evidence from a distance of more than two miles their railway fares actually paid or (where a railway is not available) reasonable expenses of conveyance actually incurred: provided (1) that the railway fare, except for special reasons allowed by the court, shall be third-class fare and that if return tickets are available only return rates shall be allowed; (2) that the expenses of conveyance otherwise than by railway shall not in any case (except where a special conveyance is required for a witness suffering from serious illness) exceed 1*s.* a mile one way. Such expenses shall be allowed separately as mileage." This means that in the majority of cases third-class railway fares and no more will be allowed to medical witnesses where railways are available. We have before us in addition to the regulations a memorandum issued by the Home Office to those who are to administer them and upon this head the following observation is made: "The question whether a railway fare in excess of third class is to be allowed in any case will mainly depend on what may be reasonably supposed to be the witness's ordinary habit and practice First class fare should not be allowed even to a professional witness unless there is reasonable ground for supposing that he ordinarily travels first class." This, we maintain, is not just to the professional witness who as a general rule is a medical man. Without discussing the "ordinary" habits of medical or of other professional men, we would point out that few of them would care to travel to and from an assize town in third-class carriages, crowded with police and other witnesses for the prosecution or defence, with accused persons on bail, and with prosecutors, male or female, whom they have examined for the purpose of giving evidence and to whom they are well known by sight. First-class fares should be paid without question to all professional witnesses, or, indeed, to all witnesses for whom they are reasonable in the circumstances described. The new regulations take the place of a mileage of 3*d.* each way so that they show a decrease of allowance where railway fares are necessary and an increase where railways are unavailable.

With regard to the expenses of professional witnesses detained for the night away from their homes, the regulations are silent while they provide for those of other witnesses. This means that the medical man will not in future on such occasions be allowed the ridiculous sum of 2*s.* 6*d.* to which he has been accustomed but will have to pay his hotel bill out of the extra guinea which he receives when his residence is more than three miles away. This is a gain to a certain extent but here again chance is left to determine the amount which the witness is to have. In other words, where the trains happen to be so arranged or the distance chances to be so great that the medical man is kept from returning home (to his own increased inconvenience) he will further have to spend a large proportion of the amount paid to him by way of compensation in defraying the cost of his necessary board and lodging.

One more matter remains for comment. It will be observed by those who study the new regulations that a recommendation of the committee which considered the conditions until recently prevailing has been ignored. This was that "for a medical examination in cases of sexual and kindred offences there may be allowed a special fee of one guinea for each person examined in addition to any allowances for giving evidence." An explanation is to be found in the memorandum to which we have already referred and we are glad to have it before us. The memorandum says: "Were this fee inserted in a table of fees to witnesses it would, of course, be payable only where the examination leads to a prosecution in which the medical man who made the examination is called as a witness. It appears to the Secretary of State to be wrong in principle that a medical man should be placed in the position of earning a fee if he recommends a prosecution and of receiving nothing if his report negatives the institution of proceedings. In such cases the medical man makes the examination as the adviser to the police or to the prosecutor, and he is entitled to receive an appropriate fee whether the examination is or is not followed by criminal proceedings.' The difficulty which arose not long ago in Suffolk in obtaining any medical man to make an examination in connexion with an alleged sexual offence was largely responsible for the appointment of the departmental committee which made the recommendation quoted above, and we would suggest that all medical men likely to be summoned to make the examinations referred to should note the terms of the Home Secretary's memorandum and should consistently decline to make such examinations whenever they have reason to believe that they will not be paid a separate and adequate fee for doing so.

We shall observe with interest the application of the new regulations to medical witnesses in petty sessional courts and at quarter sessions and assizes during the year which has now commenced. The medical profession perhaps gains more by them than does any other profession or employment but even when we admit this we are entitled to say that the gain is not great and that assisting the cause of justice in the criminal courts will remain in many instances an unpleasant duty involving considerable anxiety and trouble, together with pecuniary loss, for which but inadequate compensation is provided.

THE REGIUS PROFESSORSHIP OF MEDICINE AT OXFORD.

A MEETING of the medical graduates of the University of Oxford was summoned at very short notice for Tuesday afternoon last to consider the question of the appointment of a successor to Professor Sir John Burdon Sanderson who is retiring from the Regius Professorship of Medicine. Sir WILLIAM S. CHURCH, President of the Royal College of Physicians of London, took the chair, and 40 out of 60 specially invited graduates, practically all of whom are engaged in teaching, were present, the names representing some of the best known members of the medical staffs of the metropolitan hospitals. Sir William Church made a brief exposition of the situation, showing that it was intended to recommend Dr. J. Ritchie, the present Reader in Pathology, to the vacant post. The following statement, after some discussion, was then agreed to and signed by all present save two or three:—

> We learn that it has been suggested by certain teachers in Oxford that the present Reader in Pathology should be appointed Regius Professor of Medicine. We understand that the chief argument in favour of that proposal is that in this way the emoluments of the chair of medicine might be made to supplement the income of the Reader in Pathology. We beg leave to protest very strongly against this proposal for the following reasons:—The work of the medical student of Oxford falls into two parts; the first part is preparatory and done in Oxford, the second part is clinical and done elsewhere at the large clinical schools. The first part is represented in Oxford by the professors of the various sciences; the second part can only be represented by the Regius Professor. The Regius Professor is responsible for the organisation, direction, and conduct of the final examinations in Oxford, which give the licence to practise, and should himself take part in them as the Regius Professor used to do. He has also to adjudicate and advise the University upon the theses presented for the M.D. degree. The Regius Professor ought, therefore, to be a physician of great experience in clinical work and clinical teaching; he ought to be thoroughly familiar with the system of instruction at the large medical schools and with all the details of the student's clinical work. [illegible] fully conversant with the requirements of the [illegible] bodies and of the Medical Council. He ough [illegible] knowledge to enable him to guide wisely the deliberations of the board of the faculty of medicine in these respects and to bring into harmonious relation the work of the student of medicine in Oxford with his work in the clinical school. As the Regius Professor is the representative of the University in medicine, not in Oxford only, but in the world at large, he ought to be a man of established reputation in medicine and one who could worthily uphold the dignity of the University in the estimation of the profession and of the public. He ought to be a man who could be accepted as the leader and representative in Oxford of the medical graduates, and one to whom they would all with confidence give their loyal support, for without this support the medical school in Oxford cannot prosper as it should. On these grounds we think it desirable that the Regius Professor should, if possible, be an Oxford man. The proposal to convert the Regius Professorship of Medicine into a professorship of any single branch of medical study is a question of vital importance to the status of medicine in the University and to the welfare of the medical school. We do not ourselves think this change desirable, but it is, at any rate, a question not lightly to be decided. The Regius Professor has important practical duties to discharge in Oxford. He alone is in a position to coördinate the various departments forming the medical curriculum, a task for which technical knowledge and wide clinical experience are essential.'

The following two motions were passed:—

> (1) That in the opinion of this meeting the Regius Professor of Medicine should be a physician who is representative of medicine in its widest sense. (2) That it would be detrimental to the best interests of medicine in Oxford if the Regius Professorship were converted into a professorship of any one branch of medical study.

A deputation has been appointed to wait upon the Chancellor of the University, with whom Sir William Church is already in private correspondence. This deputation will express the views of the meeting of medical graduates. The question of suggesting any person to fill the appointment, it is agreed, shall be left to the discretion of Sir William Church. Throughout the meeting no name was mentioned and no personal references whatever were made to Dr. Ritchie, the objection to his appointment being wholly upon public grounds.

THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1902.

PART I. REPORTS.

FIRST NOTICE.

THE annual report of the Chief Inspector of Factories and Workshops for the year 1902 consists of (1) The general report on the factory department during the year with eight appendices which deal respectively with: (i.) Laundries connected with religious and charitable institutions. This is a circular addressed to the managers of these undertakings asking if they wish to receive visits from the factory inspectors or from a woman inspector. It may be here said that various answers were returned and it was found in the institutions which were visited that the management was usually satisfactory. (ii.) Ventilation: a digest of results of analyses of air in factories and workshops, based upon the Report of the Ventilation Committee. This is a valuable table showing in detail the effects of artificial ventilation in cases in which gas is and is not used. The air examined was taken from factories and workshops used for weaving, tailoring, cotton-spinning, and a variety of other trades. (iii.) The particulars of a prize given by the Society of Arts for a dust arresting respirator to be used in dangerous trades. The prize consists of a gold medal or £20 in cash and the details of the competition may be obtained by anyone who applies to the secretary of the society, John-street, Adelphi. (iv.) Sanitary accommodation orders dated respectively August, 1902, and February, 1903, with a circular issued on Feb. 16th, 1903. The latter is of interest because it gives a definition of what in the opinion of the Home Office is meant by the words "sufficiently lighted" when applied to sanitary conveniences. These words we are told do not require that a brilliant light should be provided "such as would be required for reading." In some cases the conveniences are now left in total darkness and this will [illegible] longer be allowed. (v.) "The suggested [illegible] for underground bakehouses" is a paper which contains useful rules in regard to the construction, lighting, and ventilation of underground bakehouses written for [illegible] guidance of medical officers of health in advising sani[illegible] authorities as to the conditions needed in order to conform with the requirements of the Factory and Workshops Act. The recommendations made in this paper were adopted [illegible] the Incorporated Society of Medical Officers of Health [illegible] their general and uniform acceptance throughout the [illegible] would prove of service to the community at large. (vi.) [illegible] circular was issued to the manufacturers of earthen[illegible] and china in April, 1902, and a copy of this is given [illegible] the report. The determined fight made against the [illegible] Office draft rules is now a matter of history. (vii.) [illegible] regulations in regard to file cutting. (viii.) A synopsis of requirements of "particulars" to be supplied by manufacturers in regard to piecework in various industries. [illegible] the past weavers and hosiers have perhaps suffered most from the chicanery of their employers.

(2) The sectional reports (pp. 1–295). The reports made by the superintending inspectors of the five divisions into which Great Britain and Ireland are [illegible] by the principal woman inspector, the examiner of particulars, the inspector of humid textile fabrics, electrical inspector, and the medical inspector. The [illegible] of the last named contains appendices on anthrax [illegible] horsehair, and on the disinfection of horsehair—subjects [illegible] which attention will be given later,—on the Belgian [illegible] factories, and on the process of "vulcanising" by [illegible] carbon disulphide.

(3) Special reports (pp. 296–335). These are three [illegible] number and deal respectively (i.) with dangerous [illegible] injurious processes in the enamelling and tinning of [illegible] (ii.) methods of removing dust in iron foundries and mac[illegible] shops, and (iii.) ship-building accidents.

(4) Statutory orders (pp. 336–347). The orders

ring the year by the Board of Trade and the cal Government Board for Scotland make regulations regard to: (i.) Workshops used as sleeping places.) Newspaper printing. (iii.) The standard of ventilation be adopted in certain humid textile factories. (iv.) Form requisition to be used for obtaining birth certificates in otland when they are required for purposes of the Factory d Workshops Act. A similar regulation was already force in England but not in Scotland (for the power making the order was vested in the Local Government [illegible] as to lime washing [illegible] (vi.) Regulations [illegible] ive hours' spell." [illegible] l Sunday employ- ent in creameries. (viii.) Conditions of special exemption regard [illegible] gulations in regard to ertime [illegible] (x., xi., xii.) Regulations as [illegible] wages for labour on ains, anchors, cast gear, locks, and latches. (xiii.) Regula- ons as to night work in lead and zinc. During the year the llowing processes were officially certified as "dangerous" ith a view to the issue of regulations in regard to them; .) The manufacture of felt hats with the aid of inflammable lvent. (ii.) The process of file cutting by hand. (iii.) The ocess of loading, unloading, moving and handling goods , on, or at any dock, wharf, or quay, and the process of ading, unloading, and coaling any ship in any dock, arbour, or canal. This may be fittingly described as a large der. It will doubtless prove of use but anyone who has en a supe[illegible]pping will at once e that an [illegible] is in many cases solutely [illegible] loading of ships ith sand and ballast in river estuaries is a most irregular dustry both in point of time and of place.

The important part of the report which deals with the utine work of the superintending inspectors naturally cupies a large part of the book. On a former occasion me account was given in THE LANCET[1] of the way in which e country was partitioned into five great "divisions" each which is presided over by a superintending inspector and me reference was made to the distribution of the various ades which came within the purview of the officers of the oard. It is needless to travel again over the same ground nd it is impossible to refer more than briefly to the work hich has been accomplished during the time under review. here is less cause to regret this because in the present port for the first time the superintending inspectors' marks are grouped under distinct headings and it is erefore easy for any intelligent reader to find without reat loss of time any information contained in the ports which he wishes to learn. We must congratulate r. B. A. Whitelegge in having at length carried out n improvement on the necessity of which we have ad more than once to insist, and we may hope that his change will naturally lead to the further advance of iving a complete index which would greatly add to the value f the reports for purposes of reference. At the end of the ear 1902 there were 100,424 factories and 145,721 work- hops on the registers of the department and the number f visits paid to them by the inspectors amounted to mething like 350,000. It seems rather curious that lthough the Factory and Workshops Acts have been made r the protection of the workers yet in some cases the tter connive at, and even appear to encourage, irregu- rities or, to put it more strongly, illegalities which e practised by the employers. The most remarkable xample of this is the practice of "time-cribbing," as it is lled—a system by which machinery is run for a period in cess of that allowed by the law and in consequence of hich the wor[illegible] period in excess of e time allo[illegible] of the number of urs for wh[illegible] e referred to the atter before. It has proved that the paltry fines incurred the employers when they are convicted of the theft are ite inadequate.

It is interesting to note that of late there has been a ten- ncy to transfer large works from the Midlands to the coast order to save the great expense incurred in railway arges for transit and to escape from heavy local rates.

The number of accidents reported during the year was 395 and of these 1110 were fatal. The particulars of incidence of these are reserved for the second report.

The chief inspector of the north-eastern division, Mr. W. A. Beaumont, deals at length with the causation of some of the more common accidents. Only a few of the best chain makers, it seems, will guarantee the strength of the goods which they supply and it is suggested that "payment by piece encourages bad or slipshod work in chain making." As a result of his experience Mr. Beaumont has drawn up a number of suggestions in regard to prevention of accidents from the fracture of lifting tackle. The matter is one of such urgency and importance that it seems that some regulations [illegible] for all ropes and chains used in a factory; (2) that every chain should be numbered and a record kept of its use; that the user should also be informed of the safe working load for a chain or rope; (3) that every chain should be periodically annealed and examined and that a wedge-gauge may be used in each link to give an indication of the amount of wear—when this exceeds a certain allowance the link should be removed from the chain; and (4) that ropes should also be periodically examined and when they exhibit the least sign of deterioration they should be burnt to prevent further use.

The least satisfactory part of Dr. Whitelegge's report is that which deals with the impurity of the air of factories and workshops and with ventilation. It is evident from the report that the inspectors are encouraged to neglect, or at least to abstain from, taking specimens of air from workshops at all times. We are by no means prepared to admit that the standard of air (as judged by the amount of permissible impurity on de Chaumont's method) adopted as legal is too high. The fight against the legality of the continued existence of fœtid air in workshops and factories has been a long one. Thanks to the persistent efforts of those who had the good of the work-people at heart, and particularly to Sir Henry Roscoe, the statute-book was ultimately enriched by an Act the provisions of which rigidly carried out would have proved to be the greatest blessing. An attempt is apparently now being made by those appointed to carry out the working of the Act to evade its provisions, or, as Dr. Whitelegge calls it, "to deviate somewhat from the letter of the law."

The report of His Majesty's women inspectors of factories is much more diffuse than that of the other inspectors but it contains some interesting details. Amongst other things an account is given of modern dressmaking, from which it appears that Englishwomen are using more and more ready-made goods of foreign origin and that the more expensive of these goods come chiefly from Paris and from Vienna; whilst the cheaper are made in England. The London dressmaker is being ousted by factory work. "For good or for evil," and in the opinion of the chief woman inspector "on the whole decidedly for the good of workers and consumers, the great mass of our countrywomen of artisan and manual labouring classes and of the upper and middle classes are already being largely clad in ready-made dresses and mantles and millinery supplied by factory organisation."

A curious and interesting note is given on the decline of a very old industry—the manufacture of clay pipes. The increased use or abuse of cigarettes is, of course, one obvious cause of this but another is mentioned which would hardly have been suspected. It is said that the working of the Act prohibiting the sale of alcoholic drinks to children has had a great effect in the same direction. The youngsters whose former duty it was to fetch the evening beer were accustomed to beg for a pipe, and under the new law it is much to be feared that the instructive and pretty practice of blowing soap bubbles will become a lost art.

Electrical generating [illegible] stations were brought under t[illegible] Office under the Factory an[illegible] it may be remembered came into operation on Jan. 1st, 1902. Mr. G. Scott Ram was appointed as electrical inspector by the Home Office. He entered upon his duties in May and his first report therefore embraces a period of eight months. The increased and increasing use of electricity will make this new department an extremely important one and it may be useful to describe briefly the condition of things which Mr. Ram found on beginning his duties. In the first place it must be pointed out that from a legal point of view a distinction must be made between electrical stations which supply energy for public use and sale and those which belong to industrial undertakings or to private individuals and which supply electrical energy for their own use. The "public" undertakings, as they may be called, are in general working under provisional orders of the Board of Trade and include the electric supply companies and not a few local authorities. Amongst the "private" undertakings are included engineering works, dock companies, factories, and railway companies—except those railways which use electrical energy as the motive power. It is, moreover, held that electrical stations which actuate traction do not come within the scope of the Act. There is, however, an increasing number of stations where the power is generated both for traction and for public supply and these naturally come under the inspection of the factory department.

---

[1] THE LANCET, Jan. 31st, 1903, p. 325.

Mr. Ram commenced his duties by visiting a large number of representative types of generating stations in England, Ireland, and Scotland. He was chiefly concerned to notice what precautions were observed for the protection of the workmen, to find out the conditions under which the work was carried on, and to see whether he ought to advise for adoption any special regulations and, if so, what these should be. Mr. Ram considered that it was also of interest to ascertain how far the recommendations drawn up by the Board of Trade Dangerous Trades Committee (1897) "are now applicable in view of the advance made in electrical matters since that date." Professional electrical engineers as a body are strongly of opinion that a higher pressure than that recommended as a maximum shall be allowed and Mr. Ram appears to feel in no way bound by the recommendations of 1897.

The result of the general inspection of the stations visited showed that there were a great diversity of operation and an entire absence of any standard method even amongst the factories which were nominally worked on the same system. This state of things is said to be due to the rapid growth of a new industry and to the introduction into this country of large quantities of machinery of foreign manufacture differing in their modes of work from those previously in use here. Mr. Ram has classified and grouped, according to their electrical characteristics, the systems which he found at work in the course of his survey. It may suffice to say that he found four systems in use for the supply of the continuous current and nine in the case of the alternating current, and that he was able to summarise the distinctions as to the electric pressure of the systems into three groups: 1. Low-pressure system, in which the difference of electric potential is nowhere greater than 500 volts in the case of the continuous current and 250 in that of the alternating current. 2. High-pressure system, in which the difference may exceed the limits in Group 1 but does not exceed 3000 volts. 3. Extra high pressure in which the difference of electric potentials exceeds 3000 volts. Groups 2 and 3 are based on Board of Trade regulations, whilst Group 1 is formed "for convenience" but the term "low pressure" does not imply any degree or property of safety.

Amongst the methods of trade development which will require supervision it is evident that the use of superheated steam is important. It is now in use up to a temperature of 800° F. and a marked economy in the amount used is effected by its use at high tension. The new dangers evolved are evident. A leaky joint will with such a pressure be more serious, an explosion more terrible. The effect of continuous high temperature on the strength of materials will, Mr Ram says, "have to be carefully watched." This may be taken to mean that the danger is foreseen and the inspector has issued his warning. It is, naturally, not proposed that the President of the Board of Trade should personally watch such a boiler or have one on the premises at Whitehall, and should such a duty fall within the scope of his office it is not improbable that he would see the desirability of having a scientific investigation immediately made into so serious a matter. Under the existing conditions it seems not improbable that the question will receive no further notice until a ghastly explosion calls the "attention of the public" to it.

The number of accidents reported in connexion with electrical stations and electricity supply companies and local authorities during the year was as follows:—"Mechanical" (under which heading are included those which took place in connexion with steam engines, boilers, dynamos, and "various"), 106, five of which were fatal. Electrical accidents: burns, 19 cases, in three of which there was injury to the eyesight and one was fatal; and shock, 11 cases, four of which were fatal. In regard to the mechanical accidents the table given is not very complete for no less than 88 of the 106 cases are placed under the heading "various." In his next report no doubt the electrical inspector will insist on being supplied with more complete information and it would not be fair to him to be severe concerning the omission of details which may have been improperly withheld or carelessly noted by those responsible for the reports which were made to him.

In connexion with the increasing use of higher electrical pressures it may be remembered that at the present time the pressure of a supply which may be delivered to a consumer is limited to 250 volts, except in cases in which the express approval of the Board of Trade is obtained. "It is becoming increasingly common," Mr. Ram tells us, "for supplies of electrical energy to be given to consumers at from 250 to 500 volts for power purposes, presumably with the approval of the Board of Trade in each case."

Mr. Ram thinks that there is no objection to the use of the stronger current if the plant is thoroughly efficient and the conditions which are laid down by the Board of Trade are loyally carried out, but he points out that some companies are seeking to supply their customers at high pressure at the motor terminals in order to save the losses connected with the transformation of the current to lower voltages. The powers of the Board of Trade are limited, as we have seen, and the regulations which can be imposed apply directly only to the companies which give the supplies and a consumer may therefore transform the energy to as high a pressure as he pleases. There is, moreover, no legal limit to the pressure at which electrical energy may be generated in factories. In the early days of electric lighting a pressure as high as 2000 volts was often used in the circuits connecting arc lamps and Mr. Ram found that a certain number of these installations still exist and that many of them are in an unsatisfactory state.

The electrical engineer ends his report by giving a summary of conditions which frequently exist and have already caused accidents or which give rise to unnecessary risk. The list deals with switchboards, generating plant, and sub-stations, and, in conclusion, advice is given on questions of general management on the suggestions made. The attention now called to these dangers should prove of great service if the teaching they convey be not neglected. Mr. Wilson (inspector of factories for the Newcastle-on-Tyne district) points out that there is at the present time a feeling of general uneasiness among workmen as to the possible dangers of shock and this is quite natural. There is also, he says, a remarkable ignorance of the laws of electricity amongst all classes—"masters, managers, and men." From this he argues that regulations in regard to its use in factories would be welcomed both by the employers and the employed. It is to be hoped that that suggestion will be carried out.

The general report of the medical inspector is, as usual, of great interest and has the merit of containing for the first time a short but sufficient index. Of the four appendices two deal with anthrax, the third with the Belgian [illegible] factories, and the remaining one with the "vulcanising process (a translation of a decree of the German F[illegible] Council concerning the erection and management of industrial premises in which indiarubber goods are vulcanised by means of carbon disulphide and chloride of sulphur). It is satisfactory to note that the number of cases of lead poisoning has diminished in each of the 14 branches of industry in which notification is compulsory. The number of reported cases has, indeed, steadily diminished during the last four years, the figures being as follows: for 1899, 125[illegible]; for 1900, 1058; for 1901, 863; and for 1902, 629. It is hardly necessary in this place to quote the figures [illegible] the incidence of the poisoning in the various trades and it may be sufficient to mention that the diminution is [illegible] marked in the manufacture of electric accumulators, the smelting of metals, and in file cutting. It is [illegible] marked in coachmaking and in printing. Dr. T. M. [illegible] very justly points out that too much stress ought [illegible] to be placed on slight improvements which extend [illegible] so short a period as a year and it cannot be too strongly stated that lead poisoning is still much more prevalent [illegible] it should be. It is somewhat remarkable that alt[illegible] the notification of lead poisoning in house painters is [illegible] obligatory more notifications are, in fact, recorded of [illegible] employed in this trade than there are of persons [illegible] in any one industry which is registered under the F[illegible] and Workshop Act.

It is extremely doubtful whether the pernicious effect l on this large class is generally recognised, although it ully appreciated by those who have had a prolonged erience of the occupations and diseases of the patients ted in the metropolitan hospitals.

recent decree issued by the French Government is in ance of any measure which has been taken in this ntry for the protection of house painters. It provides that white lead shall not be used before it has already worked up in oil and (2) that it shall not be ipulated by hand; (3) that in processes of rubbing n and in all operations in which white lead is used the loyers shall provide overalls for the men, shall see that are washed and kept in good repair, and that they are n; (4) that articles necessary for insuring cleanliness to be provided for the workers at the place at which they working; (5) that the implements of work are to be t clean without dry rubbing; and finally (6) it is the of employers to post the notice containing these lations at the place in which the workers are engaged

oisoning by phosphorus has become rare and only one case was reported during the year. The patient was foreman of a "boxing" department, the part of the ory devoted to the packing of matches. The case was of necrosis of the lower jaw. Two patients died from eumonia accelerated by suppuration," the result of sphorus necrosis of many months' duration.

ight cases of mercurial poisoning were reported. Of e, two occurred in hatters' foremen—one was a chronic and the other a second attack. One case occurred in a tograph engraver, aged 23 years, who used perchloride of cury in the course of his work in which he had been aged for four years. Three cases occurred in electric re factories. There was one chronic case of a thermometer er and one of a man employed in an explosives factory re fulminate of mercury was used in manufacture.

oisoning by arsenic comes under the notice of the factory ectors in two distinct forms—(1) poisoning from niuretted hydrogen and (2) from arsenical salts. In first form of poisoning almost all the cases notified have contracted in factories and workshops in which there been a deficiency of ventilation, either because the ce used was insufficient or because the provisions made the removal of gases was inadequate. Poisoning from arsenical salts is caused by the work done in its action, in the manufacture of Paris or emerald green (a ll industry), and in the manufacture of sheep dip—a pound which contains arsenite of soda.

nthrax since its first discovery has always attracted a ree of attention out of all proportion to the mortality ch it has caused and it is indeed well that this is the case care bestowed on the preventive measures which have taken has been rewarded with considerable success. he writers on the diseases of animals are to be credited rax was one of the most common and one of the most ible of the epizootics of the Middle Ages and it is by no ns improbable that amongst men some of the epidemics ickness may have been due to the same cause. During year the number of cases of anthrax reported under the tory and Workshop Act was not very great. In the year it amounted to ten which occurred in trades in which manipulation of horsehair forms part and 12 in work- ple engaged in the woollen industry. 11 cases occurred ngst workers in trades connected with the dressing of s and skins and two cases occurred in porters engaged nloading oranges. Of the three remaining cases two rred in men who had been employed in unloading oes of grain and wool respectively, and one case was ibuted to the handling of buffalo-horns which had come China. Altogether there were 38 cases.

r. Legge points out that it is impossible to forecast with accuracy what may be the incidence of anthrax in the re and, anticipating the information which will be ished in the report on 1903, he tells us that during first two months of that year as many cases have been rted from the Bradford district as occurred there in the ious year. The columns of THE LANCET have more ntly recorded other outbreaks.

iere is at the present time no control over the [illegible] and it is therefore not pos [illegible] iterfere in the matter. A [illegible] ted with anthrax and ma [illegible] er to which he submits himself and his workpeople. state of things cannot be considered other than un- factory and it may be hoped that it will be altered.

There has in the past been some difficulty experienced in the disinfection of hair and of wool; some of the methods tried have proved to be inadequate and others have injured the goods operated upon. The present volume contains a valuable paper, the second of a series[2] by Mr. Albert Webb of Worcester, who employed Mr. Cecil Duncan, the Worcester county analyst, to carry out a series of experiments. These show beyond doubt the limitations of the use of steam disinfectors and it is to be hoped that the whole paper will meet with the recognition which it undoubtedly deserves.

MEDICINE AND THE LAW.

Burroughs, Wellcome, and Co. v. Thompson and Capper.

THE issues raised in this trial were of importance both to the plaintiff firm and to the medical profession. The former brought their action in order to establish their right to the exclusive use of the words "tabloid" and "tabloids" to describe goods of their manufacture, and as their trade-marks, and the defendants denied this right and sought to have the two words expunged from the register of trade-marks as having been wrongly placed there. The plaintiffs had expended energy, care, and skill, as well as capital, in building up a trade indissolubly connected with the word "tabloid" and many medical men had been accustomed to use that word in prescribing when they desired to specify the drugs of Burroughs, Wellcome, and Co. to the exclusion of all others. To the general public, particularly to those engaged in mercantile pursuits, the case is worthy of attention because it illustrates the defects of a system which allows a trade-mark duly registered in the Government office established for that purpose and used consistently ever since with the fullest possible measure of publicity to be called in dispute 20 years later and possibly to be removed from the Register altogether to the very serious injury of the trader who has expended his capital and his energy in connexion with it. A trade-mark must consist of at least one of certain essential particulars specified in the Patents, Designs, and Trade-marks Acts, 1883 and 1888. Under the latter Act there may be registered as a trade-mark "an invented word or invented words," this expression being substituted for "a fancy word or fancy words not in common use" which corresponded with it in the Act of 1883 The word "tabloid" was registered as a trade-mark in 1884, and the word "tabloids" in 1885, and therefore what the court had to decide was whether "tabloid" or "tabloids" was "a fancy word not in common use" at those dates. With regard to this there was not only the evidence of Mr. H. S. Wellcome as to the invention of the word "tabloid" by him and of those who had associated it only with his products but there was also the testimony afforded by dictionaries and literary works in which it was to be found after that date, whereas no appearance of it in print before could be shown, and it was further proved that where dictionaries had given "tabloids" as a word in common use and of general application in the manufacture of drugs the publishers had either corrected the error on having it pointed out by Messrs Burroughs and Wellcome or had undertaken to do so. With regard to this, the question of common use as distinct from that of general application to drugs, Mr. Justice Byrne observed in his judgment: "When the word 'tabloid' was first mentioned I quite thought it was a common dictionary word in the language long before 1884, but I am satisfied that this was really due to my acquaintance with the word as used in connexion with the compressed drugs of the particular shape I have described which have become so well known since the year 1884." In a later passage he observes: "Mr. Walter (counsel for the defendants) ingeniously suggested that the plaintiffs have sought to rob the English language by preventing its natural development, in endeavouring to appropriate such a word as 'tabloid,' which he puts as being a natural development of the word 'table' or 'tablet,' but I think it is more correct to say that the plaintiffs have made a gift such as it is to the language, while reserving a special use of it to themselves." There can indeed be no doubt that Mr. Wellcome was the inventor and first user of the word tabloid, which has been found expressive, or to use a slang expression has "caught on," and so has been adopted into the English language. With regard to this Mr. Neville, K.C. (counsel for the plaintiffs) submitted to the judge that "tabloid" was so clearly within the Act of 1888 and could so certainly have been properly registered as an "invented" word, had that Act been in force in 1884, that it should be allowed to remain upon the Register even if it did not comply with the requirements of the earlier statute. As, however, Mr. Justice Byrne was satisfied that "tabloid" was "a fancy word not in common use" in 1884 this point did not arise. In so holding he had to consider a number of decisions which have interpreted the expression used in the Act. In particular he had before him the case in which the court was asked to expunge the trade-mark "bovril" from the Register. In that it was laid down that the test was what an intelligent jury would say if they were asked whether the word bovril was a fancy word not in common use at the date upon which it was registered. In the Bovril case, as in that of "tabloids," the apparent derivation of the word was gone into and the question was raised whether it was too "descriptive" of the matter to which it was applied to be a good fancy word, but it was held that though "bov" might suggest an ox the word "bovril" at the time of registration was not descriptive and this decision was followed by Mr. Justice Bryne who said: "I think the case is near the line, but treating it as a matter of fact in the particular case I come to the conclusion that in March, 1884, the word was not 'really intelligibly describing the thing sold,' which is the way in which Lord Lindley in the Bovril case puts the form of direction to the jury."

---

[2] The first report was printed on pp. 472–73 of the annual report of the year 1900.

To whatever extent the decision of Mr. Justice Byrne may be held to be one of law it is no doubt subject to revision upon appeal and, as it is possible that such appeal may follow, the law applied in it to the word "tabloid" has been stated above without criticism. With regard to facts held by the learned judge to have been proved, which include those relating to the "passing off" of other goods as those of the plaintiffs' firm, Mr. Justice Byrne expressed himself as perfectly satisfied with the evidence upon this particular topic. He drew special attention to those instances as to which evidence was given where the initials "B. & W." were added to the word "tabloids" in the request for the goods named. In this connexion his lordship said: "I have specially mentioned these three cases because there was a passing off where the goods were not denoted as 'tabloid' or 'tabloids' only but in such a way as to make it absolutely certain that the plaintiffs' goods were referred to by the use of their name or initials. There were nine other cases where the goods required were referred to as 'tabloid' or 'tabloids.' In all 12 cases were proved." The injunction which he granted with regard to the course of dealing thus shown to have been carried on by the defendants will be of value not only to the firm which has obtained it but to the medical profession at large and to their patients. It is not necessary to go into the reasons which may cause a medical man to specify the drugs of Messrs. Burroughs, Wellcome, and Co. or of any other firm in writing his prescription in order to say that he does so with good cause and that he should be able to do so with confidence that his direction will be carried out. On the whole, we have no doubt that the success achieved by Messrs. Burroughs, Wellcome, and Co. in their recent action will prove to be both to them and to others worth the anxiety, trouble, and money which it must have cost them. We may also be allowed to express the opinion that the state of uncertainty which affects a trade-mark even after it has been duly placed upon the Register is not satisfactory or desirable. Registration even after a number of years does not protect the mark from liability to be removed by the order of the court. Such statutes as those relating to patents and trade-marks are drawn by eminent experts in legal draughting and are no doubt subject to rigid scrutiny before they become law. It is, however, a matter of regret that the use of meagre and ambiguous phrases such as those which we have quoted with reference to trade marks consisting of words should leave the law in a state of uncertainty continuing for many years and necessitating for its elucidation the expenditure of thousands of pounds by private members of the community.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9378 births and 5944 deaths were registered during the week ending Jan. 2nd. The annual rate of mortality in these towns, which had been 19 2, 17·8, and 15·4 per 1000 in the three preceding weeks, rose again last week to 20·6 per 1000. In London the death-rate was 21·1 per 1000, while it averaged 20·3 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 10 0 in Hornsey, 11·5 in King's Norton, 11·9 in South Shields, 12·7 in Handsworth, 13·6 in Coventry, 13 9 in Northampton, 14·1 in Leyton and in Derby, and 14 2 in Walthamstow; the highest rates were 24·1 in Stockton-on-Tees, 24·2 in Ipswich, 24·5 in Newport (Mon.), 24·9 in Brighton, 26·8 in Liverpool, 31·3 in Merthyr Tydfil, 32·4 in Preston, 33·6 in Wigan, and 35·1 in York. The 5944 deaths last week included 495 which were referred to the principal infectious diseases, against 423, 423, and 389 in the three preceding weeks; of these 495 deaths 152 resulted from measles, 135 from whooping-cough, 68 from diphtheria, 64 from diarrhœa, 38 from "fever" (principally enteric), 35 from scarlet fever, and three from small-pox. *No death from any of these* principal infectious diseases was registered last week in Tottenham, Hastings, Brighton, Bournemouth, Devonport, Burton-on-Trent, Grimsby, Derby, Wallasey, Warringt Huddersfield, Middlesbrough, Tynemouth, or Newp (Mon.); among the other towns the highest death-rates fi these diseases were recorded in Willesden, Birmingha Bootle, Wigan, Blackburn, Preston, York, and Stockton- Tees. The greatest proportional mortality from mea occurred in Willesden, Ipswich, Birmingham, Blackbu Preston, Leeds, Rotherham, and Cardiff; from sca fever in Wigan; from diphtheria in Reading; fr whooping-cough in Portsmouth, Walsall, Liverpool, Boo Wigan, Leeds, York, and Swansea; from "fever" Bootle; and from diarrhœa in Southampton, Rochdale, Stockton-on-Tees. Of the three fatal cases of sm pox registered in these towns last week one belon to Nottingham one to Bolton, and one to Sunderland. number of small-pox cases remaining under treatment the Metropolitan Asylums hospitals, which had been 26, and 27 on the three preceding Saturdays, had decli again to 26 on Saturday last, the 2nd inst.; four new ca were admitted during the week, against two, six, seven in the three preceding weeks. The number of sca fever cases in these hospitals and in the London Fe Hospital was 1632 at the end of last week, against 17 1654, and 1617 at the end of the three preceding wee 194 new cases were admitted during the week, agai 173, 188, and 142 in the three preceding weeks. deaths in London referred to pneumonia and disea of the respiratory system, which had been 417, and 271 in the three preceding weeks, rose ag last week to 404, and were 61 above the num in the corresponding period of last year. The causes 97, or 1·6 per cent., of the deaths in the 76 large tow last week were not certified either by a registered medi practitioner or by a coroner. All the causes of death w duly certified in West Ham, Leicester, Salford, Lee Hull, Newcastle-on-Tyne, and in 40 other smaller tow the largest proportions of uncertified deaths were registe in Handsworth, Grimsby, Liverpool, St. Helens, Barrow- Furness, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the princi Scotch towns, which had been 22·4, 20·9, and 20·8 per 10 in the three preceding weeks, increased again to 21·7 p 1000 during the week ending Jan. 2nd, and was 1·1 p 1000 in excess of the mean rate during the same per in the 76 large English towns. The rates in the eig Scotch towns ranged from 13 7 in Leith and 16·5 Greenock, to 24 6 in Glasgow and 27·9 in Perth. The 7 deaths in these towns included 26 which were referred measles, 21 to diarrhœa, 14 to whooping-cough, five small-pox, two to scarlet fever, two to "fever," and one diphtheria. In all, 71 deaths resulted from these princi infectious diseases last week, against 73, 61, and 73 in th three preceding weeks. These 71 deaths were equal to annual rate of 2·2 per 1000, which was 0·5 per 1000 ab the mean rate last week from the same diseases in

76 large English towns. The fatal cases of measles, which had been 34, 33, and 25 in the three preceding weeks, rose again last week to 26, of which 23 occurred in Glasgow and two in Paisley. The fatal cases of diarrhœa, which had been 15, 10, and 16 in the three preceding weeks, further rose to 21 last week, and included 10 in Glasgow, four in Edinburgh, four in Dundee, and two in Aberdeen. The deaths from whooping-cough, which had been 13, nine, and 16 in the three preceding weeks, declined again last week to 14, of which six were registered in Glasgow, four in Edinburgh, and four in Aberdeen. The fatal cases of small pox, which had been one, two, and four in the three preceding weeks, further rose to five last week, and all occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 192, 184, and 180 in the three preceding weeks, further declined last week to 177, but were 19 in excess of the number in the corresponding period of last year. The causes of 29, or more than 4 per cent, of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·6, 25 6, and 19 9 per 1000 in the three preceding weeks, rose again to 31·8 per 1000 during the week ending Jan. 2nd. During the 13 weeks ending on that date the death-rate has averaged 23·3 per 1000, the rates during the same period being 16 6 in London and 16 7 in Edinburgh. The 231 deaths of persons belonging to Dublin, registered during the week under notice, showed an excess of 86 over the number in the preceding week, and included 16 which were referred to the principal infectious diseases, against 11, 10, and seven in the three preceding weeks; of these, 12 resulted from whooping-cough, two from "fever," one from measles, and one from scarlet fever, but not any from small-pox, diphtheria, or diarrhœa. These 16 deaths were equal to an annual rate of 2·2 per 1000, the death-rates from the principal infectious diseases last week being 1·9 in London and 1·6 in Edinburgh. The fatal cases of whooping cough, which had been seven, four, and three in the three preceding weeks, rose again last week to 12 The deaths from measles, scarlet fever, and "fever" corresponded with the respective numbers in the preceding week. The 231 deaths in Dublin last week included 36 of children under one year of age and 60 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons were considerably in excess of the numbers recorded in the preceding week. 11 inquest cases and six deaths from violence were registered, and 82, or more than a third, of the deaths occurred in public institutions. The causes of nine, or nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: A. F. Harper to the *Melampus* and W. G. Stott to the *President* for three months' study in civil hospital (dated Jan. 7th) and F. W. Stericker to the *Doris* (dated Dec. 31st). Surgeons: H. G. T. Major to the *President* for three months' study at civil hospital, A. E. Mereweather to the *Wildfire*, and R. Thompson to the *Aurora* (dated Jan. 7th).

ARMY MEDICAL STAFF.

Surgeon-General Sir W. D. Wilson, K.C.M.G, is placed on retired pay (dated Jan. 1st, 1904).

1ST LIFE GUARDS.

Surgeon-Lieutenant Basil Pares to be Surgeon-Captain (dated Nov. 14th, 1903).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. J. R Rainsford, C.I.E, to be Colonel, vice J. F. Supple, C B., retired (dated Dec. 14th, 1903).

Colonel W. E. Saunders, C.B, is transferred from the Poona to the Meerut and Bundelkhund Districts, but will continue to officiate as Principal Medical Officer, Bombay Command, until relieved by Surgeon General Gubbins.

IMPERIAL YEOMANRY.

Westmorland and Cumberland: Surgeon-Captain J. E. Bowser to be Surgeon-Major (dated Jan. 2nd, 1904).

VOLUNTEER CORPS.

Royal Engineers (Volunteers): 1st Devonshire and Somersetshire: Surgeon-Major G. B. Fraser to be Surgeon-Lieutenant-Colonel (dated Jan. 6th, 1904).

Submarine Miners: The Severn Division: Surgeon-Captain W. L. [illegible]

Rifle [illegible] W. N. [illegible] Regiment, to be Surgeon-Captain, and to be borne as supernumerary whilst commanding the Bearer Company of the 5th London Volunteer Infantry Brigade (dated Jan. 6th, 1904). Supernumerary Surgeon Captain J. G. Fraser, commanding 5th London Volunteer Infantry Brigade Bearer Company, resigns his commission (dated Jan. 6th, 1904). 3rd (Duke of Connaught's Own) Volunteer Battalion, the Hampshire Regiment: Surgeon-Lieutenant G. F. Morley to be Surgeon Captain (dated Jan. 6th, 1904). 1st Volunteer Battalion, the Leicestershire Regiment: Supernumerary Surgeon Captain W. P. Peake, also commanding Leicester and Lincoln Volunteer Infantry Brigade Bearer Company, resigns his commission (dated Jan. 6th, 1904). 4th Volunteer Battalion, the Cheshire Regiment: Henry George Smeeth, to be Surgeon-Lieutenant (dated Jan. 6th, 1904). 5th Volunteer Battalion, the Cheshire Regiment: Surgeon-Lieutenant E. J W. Carruthers to be Surgeon-Captain (dated Jan. 6th, 1904). 1st Volunteer Battalion, the Royal Welsh Fusiliers: Captain J. E H. Davies resigns his commission and is re appointed Surgeon-Captain (dated Jan. 2nd, 1904) 4th Volunteer Battalion, the King's (Liverpool Regiment): Surg [illegible] commission (date [illegible] Volunteer Battal [illegible] Captain J. O. Wil [illegible] 1904). 1st (Inve [illegible] the Queen's Own [illegible] Colonel (Lieutena [illegible] resigns his commission (dated Jan. 2nd, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Manchester Companies: Captain J. W. Smith resigns his commission (dated Jan. 6th, 1904).

VOLUNTEER INFANTRY BRIGADE

Worcester and Warwick: Major W. J. Whitcombe, commanding Brigade Bearer Company, to be Brigade-Surgeon-Lieutenant Colonel whilst holding the appointment of Senior Medical Officer to the Brigade (dated Jan. 2nd, 1904).

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

East Surrey: Surgeon Captain (Honorary Captain in the Army) E. W. St. V. Ryan, from 16th Middlesex Volunteer Rifle Corps, to be Surgeon-Captain (dated Jan. 2nd, 1904).

NEW ARMY ORDER.

The following Army Order has been issued in India:—

> The Commander in Chief is pleased to empower principal medical [illegible] detail regimental medical officers of the Indian [illegible]
>
> [illegible] as at present.

THE MEDICAL DEPARTMENT OF THE UNITED STATES NAVY.

In the report of the Surgeon-General of the United States Navy, Chief of the Bureau of Medicine and Surgery, for 1903 the recommendation is made that as most of the naval hospitals were built many years ago modern systems of plumbing, heating, and ventilating should be installed and operating rooms and elevators provided in order to bring them up to date. It is also pointed out that the crowded condition of the hospitals renders it desirable that quarters occupied by the medical staff should be devoted to the accommodation of patients. It is stated that in order to meet the urgent need of the service for medical officers and to provide for the future Congress has authorised an increase of 150 officers in the medical corps At the same time by a wise distribution of the increase among the different grades and a re-arrangement of rank whereby rank for grade was established it placed the Bureau in a position to compete successfully with other Government services in attracting properly qualified physicians to the naval service. An important part of the report is that dealing with tuberculosis. The need of a naval sanatorium for the treatment of tuberculosis, says the report, has been demonstrated with increasing force during the past year. It had been necessary previously to 1902 to rid the service of its chronic consumptives by discharge to civil life, turning them loose to menace their home communities and to drag out their unhappy and short-lived existence as best they might. Last year arrangements were made for the admission of naval tuberculous patients to the Army General Hospital at Fort Bayard, and the Bureau is of opinion that the needs of the navy warrant the establishment of special sanatoriums as adjuncts to some of the most favourably situated naval hospitals. The experience of the past year emphasises the wisdom of the recommendations made by the Bureau for the appointment of skilled dentists at the stations where men and boys are assembled to be trained. In the report on recruiting it is shown that out of a total of 25,000 men examined 13,049 were accepted and 659 men were found to be colour-blind. The whole report shows the great progress which is being made in the medical affairs of the United States Navy.

DEATHS IN THE SERVICES.

Lieutenant-Colonel Edward Russell Cree, R A.M.C., son of the late Edward Hodges Cree, inspector-general of hospitals and fleets, R N., on Dec. 29th at Pinewood Sanatorium, Wokingham, in his forty-sixth year. He joined the army as surgeon in 1880, became surgeon-major in 1892, and lieutenant-colonel in 1900. He served in the Soudan Campaign of 1885, and was present in the engagements at Hasheen and the Tolfrek Zariba and at the destruction of Temai (medal with two clasps and the Khedive's Star) He also served in the South African War in 1899–1900, and took part in the relief of Ladysmith (mentioned in despatches).

SOLDIERS' MESSING.

With regard to the proposal recently advocated by a military correspondent in the *Times* to introduce a restaurant system of messing into barrack life, we are not informed how that system is to be carried out on field service in war. Without trained military cooks and some practical knowledge of cooking we do not see how the soldier is to be fed and his field ration cooked during a campaign, and, as it seems to us, a practical knowledge of this sort can only be acquired in time of peace.

THE MEDICAL BOARD, INDIA OFFICE

Colonel A M Branfoot, C.I E., I.M S., retired, has been appointed President of the Medical Board, India Office, on the retirement, which will soon take place, of Surgeon-General Sir William Roe Hooper, K.C.S.I.

PRESERVATIVES IN FOOD.—It is announced from New York that in the course of the practical experiments instituted by the Department of Agriculture to ascertain the effect of preservatives in food, the supply of food containing the preservative salicylic acid has had to be stopped owing to its injurious effects upon the subjects One individual, however, is stated to have benefited by taking food preserved with this acid inasmuch as the rheumatism from which he had been suffering disappeared. Food preserved with borax has also had ill effects It may be remembered that the departmental committee on food preservatives proposed to make the addition of borax compounds to cream and butter lawful so long as a certain proportion was not exceeded, and similarly it was suggested that salicylic acid should be allowed but not in a greater proportion than one grain per pint in liquid food and one grain per pound in solid food, its presence in all cases to be declared.

Correspondence.

"Audi alteram partem."

THE ADMINISTRATION OF CHLOROFORM TO MAN AND TO THE HIGHER ANIMALS.

To the Editors of THE LANCET.

SIRS,—In his letter in THE LANCET of Dec. 19th, 1903, p. 1757, Dr. W. J. Lindsay raises contentions which may be discussed with great advantage. That the administration of anæsthetics is fraught with danger in the hands of the unskilled few would deny at the present day, eve without the recent emphasis laid upon the point by Dr. A. Waller. When, however, it is suggested that such danger to be removed by improved apparatus we get upon debatable ground. The question revolves mainly around th administration of chloroform and to this I propose to confir my few remarks. Now, Dr. Lindsay's contention appears t be that safety must not depend upon the skill and care of th anæsthetist but upon the implement which he employs. Th giving of anæsthetics is mere empiricism, he says, in fac while one man can give them better than another. So long a the anæsthetist is guided by his power to estimate the exac condition of his patient, to vary the quantity of the drug h gives in accordance with the varying behaviour of the patien and the varying needs of the operation in progress, so long says Dr. Lindsay, the anæsthetist is a mere artist and not man of science. This position seems to me no more logica than it would be to maintain that surgeons are unscientifi because it depends entirely on their skill and care to wha depths the knife cuts. It might just as well be said that fo surgery to be a science the incising implement must cut t a definite depth and a definite length whenever it is applie to the skin It might be more scientific perhaps if th knife with which a surgeon opened the abdomen alway made a cut, for instance, two inches long and 10 centimetres deep whenever it was applied to the skin. Th result, however, in the case of thin persons would surel lead their friends to prefer the skill of a surgeon who wa something of an "artist" and not merely the wielder of a accurate implement. As a matter of fact such contention as this of Dr. Lindsay are not scientific because they ar based on false data. If Dr. Lindsay will guarantee tha every human being shall from the moment of inspirin an anæsthetic to the close of the operation carr on respiration in exactly the same manner, that hi respiration shall be unaffected by his physical condition by his mental nature, by the nature of the operation, or b the posture which it demands, then truly it will be scientifi to come forward with an instrument supplying perfectl regularly an unalterable amount of chloroform. Until this happens we must be able to vary our dosage within wide limits. Nothing but care, skill, and experience can enable us to be perfect in carrying this out. Those of less experience will be less unsafe no doubt if they handle an instrument that cannot supply a vapour of more than a certain strength. Such an instrument they already have in Junker's inhaler. Vernon Harcourt's is more accurate, and no doubt a modified form of Dubois would be an advantage. Yet such instruments as these do permit of variation of dosage within limits, and only experience can insure the proper use of this possible variation. The objection to their use is that in experienced hands they do not provide for as strong a vapour as may be required, in inexperienced they will insure comparative safety but only at the price of an often imperfect anæsthesia. Because the lower or even the higher animals can be very satisfactorily anæsthetised for laboratory work with these accurate instruments it by no means follows, and it is actually not the case, that they are equally satisfactory when applied to the various individuals upon whom surgeons operate. Safety and success with anæsthetics are to be found not in the apparatus but in the hands that employ it. Plenty of deaths have attended the use of Junker's apparatus. Plenty, even if fewer, may be safely predicted for any form of apparatus that is put into inexperienced hands, unless, indeed, a most imperfect form of anæsthesia is to be regarded as sufficient. The safety of the patient and the convenience of the surgeon will be better consulted if every man who undertakes to give anæsthetics is careful to acquire first a wide experience in their use and believes that if he arms himself with the most accurate and scientific instrument in the market nothing more is needed.

I am, Sirs, yours faithfully,
Cavendish place, W. J. BLUMFELD.

To the Editors of THE LANCET.

SIRS,—We note that your issue of Dec. 19th contains a letter from Dr. W. J. Lindsay in which reference is made to Mr. Vernon Harcourt's new chloroform inhaler. In connexion therewith we beg to state that we have acquired Mr. Vernon Harcourt's patent and shall be able to offer the apparatus for sale early in the new year. In the meantime we shall be pleased to show one of the inhalers to any of your readers who may call at our showrooms.

We are, Sirs, yours faithfully,
JOHN J. GRIFFIN AND SONS, LTD.
Sardinia-street, W.C.

THE BORDERLANDS OF INFECTIOUS DISEASES AND THEIR MANAGEMENT.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 26th, 1903, pp 1834–35, Dr. ement Dukes when referring to the statement contained the valuable contribution of Dr. Biss that "the constant eaking out of scarlet fever in the diphtheria wards and of [illegible] wards may be traced to some [illegible] of whose ailment had caused [illegible] oked" exclaims, "What an dictment against the management, or construction, of ese hospitals." I submit that it is merely the indictment a system and not of either construction or administra- on. Dr. Dukes does not believe in the existence of these omalous cases and asks for instances. Let me direct his tention to the report of Dr. L W. Darra Mair dealing with n outbreak of "sore-throat illness" which occurred at incoln in May, 1902. To begin with there was a division opinion as to whether the disease was or was not scarlet ver, the prevailing belief being that it was not. The pidemic claimed nearly 200 victims, of whom four died. linically a large number of the cases were scarlet fever, acteriologically none were. The disease was not contagious. r. E. Mansel Sympson thus classifies the cases which came nder his observation: (1) cases which were clinically in- istinguishable from cases of scarlet fever; (2) inter- ediates which presented sore-throat, fever, and some rash; nd (3) cases without rash.

In the first group there was peeling which took from four five weeks to complete In the second the rash was rticarial in character. In the third, in addition to fever here were sore-throat and swelling of the external glands. he complications were gastritis and rheumatism, the latter ometimes resembling rheumatic fever. The streptococcus carlatinæ was not discovered in the throat swabbings lthough other forms of streptococcus were found, but these ailed to produce any effect on animals. In three cases a [illegible] romycetes was found and to this [illegible] ak is believed to be referable.

[illegible] following year another outbreak [illegible] medical men were divided, the reponderance of opinion being this time on the side of carlet fever. On this occasion Dr. Klein failed to discover ither the streptococcus scarlatinæ or the enzyme, but umerous other streptococci were found, as were "diph- heroid" bacilli, which, however, were not pathogenic to nimals. Fortunately, very few indeed of these cases were "isolated" or Lincoln would have had an epidemic about he nature of which there would have been no question hatever. How are we to prevent the entry of anomalous ases into the wards of the "isolation" hospital? Can we ely on bacteriological diagnosis? In the case of diphtheria submit that the bacteriological test cannot be regarded as ntirely trustworthy. We are confronted by many difficulties. t has yet to be decided whether or not those organisms hich are classed as "pseudo-diphtheritic" are merely he attenuated forms of Klebs-Löffler bacilli which eed but favourable conditions to acquire virulence. Evidence, moreover, is accumulating that the Hofmann bacillus, although distinguishable from the Klebs-Löffler organism morphologically, culturally, and biologically, may become virulent by growth under favourable conditions. Again, the absence of any organism which might have etiological relationship to diphtheria cannot be taken as disproving a diagnosis of diphtheria[1] and the presence of diphtheritic bacilli in scarlet fever cannot be regarded as conclusive.

In the latter disease the point is still debateable whether or not the streptococcus of Klein is more than an associate. Difficulties (not errors) of diagnosis form only one of the objections to the aggregation of cases of infective diseases in large permanent hospitals, and I hazard the opinion that we are within measurable distance of the time when this system will be universally regarded as a blunder.

Dr. Dukes speaks of the "isolation" hospital as a "valuable institution." Now value is a demonstrable thing and the making of such a statement at the present time entails the obligation of furnishing the data on which he bases his conclusion. Those who have gone further afield than Dr. Dukes appears to have done in search of such evidence have generally been driven to an [illegible] not to be missed, [illegible] ître of the isola- [illegible] never yet been given to the world.

I am, Sirs, yours faithfully,
Nottingham, Jan. 2nd, 1904. EDWARD DEAN MARRIOTT.

To the Editors of THE LANCET.

SIRS,—The duty of carrying out an inquiry into the value of "isolation" hospitals rests upon the Local Government Board, for that [illegible] upon the [illegible] place. [illegible] while it [illegible] person from a crowded tenement is useless or even unneces- sary, all the evidence which has been accumulating since the appearance of Dr. Wilson's paper six years ago goes to show that the segregation of scarlet fever cases has been productive of no appreciable diminution in the prevalence or fatality of the disease. Is it not possible that an explanation of the paradox may be found in the hypothesis that scarlet fever, like diphtheria, may exist in a latent form and that it is by unrecognisable cases, mainly, that the infection is disseminated? Then, again, the good which it seems hospitals must do in some cases may be counterbalanced by the production of "return cases," which are probably more numerous than is supposed. For an infectious child on his return from hospital is more likely to spread infection among his school-fellows than at his home.

The experience of even one small town which has no fever hospital may be at least suggestive. In Windsor during the last ten years only two deaths from scarlet fever have occurred, that number giving a mortality-rate of 0·08 per 1000 of the child population (under ten years) and a *fatality*-rate of less than 1 per cent. of cases notified, and in only 11 per cent. of the houses affected did any further case occur after the first was notified (allowing two days for incubation). Surely, if such experience as this is general the provision of costly fever hospitals for country districts is a monstrous waste of money which is so much wanted for other and more fruitful uses.

I am, Sirs, yours faithfully,
EDW. CASEY,
Jan. 6th, 1903. Medical Officer of Health, Windsor.

ADMINISTRATION OF ANTIDIPHTHERITIC SERUM BY THE MOUTH.

To the Editors of THE LANCET.

SIRS,—A most interesting article on Diphtheria by Dr. F. Foord Caiger in THE LANCET of Dec 26th, 1903, p. 1771, induces me to mention a method of administering antitoxin which I have employed in several cases lately. This consists in giving it by the mouth. The idea occurred to me two years ago when I had a bad case of diphtheria miles off in the country. It was impossible to keep a close watch on the case and to inject the antitoxin when necessary, so I told the nurse to give it by the mouth if the temperature rose to a certain height or if symptoms seemed otherwise to indicate its use. Altogether 7000 units were given by the mouth and the patient, a youth aged 21 years, recovered without any after-effects. I have twice since given the serum in this manner and in both cases recovery has taken place. There is, fortunately, not much diphtheria in this district, so that cases are few and far between, but it struck me that, especially in children, the administration by the mouth would be much more agreeable and certainly less painful than by injection. Also, if one's case is far off it much simplifies matters and, so far as my small experience goes, may make all the difference to the result of the case.

---

[1] It is a curious fact that the lowering of the fatality rate of diphtheria since the introduction of the serum treatment has not been accompanied by a proportionate reduction in the mortality from this disease.

Taken in water the serum is practically tasteless and gives merely the sensation of something oily going down the throat. I am, Sirs, yours faithfully,

Beverley. W. HERBERT GREGORY, M.D. Edin.

THE PHOSPHATES AND UREA OF URINE.

To the Editors of THE LANCET.

SIRS,—Mr. E. G. Clayton is too diffident, he forgets how much bio-chemists have done—although more perhaps in France than in England—for medical science. Was it not Pasteur who said that osteomyelitis was simply a boil in bony tissue, and was not Pasteur right in spite of the wise men of the Académie de Médecine who declared that only a chemist could make so foolish a statement? Bouchard, calling chemistry to his aid and especially the work of Duclaux, gave precision and extension to Beneke's idea of certain diseased processes being due to retarded nutrition, and it is mainly Bouchard's chemical assistants who, free from some of the preconceived ideas of the medical man, have endowed general pathology with some of the attributes of an exact science.

If Mr. Clayton follows the evolution of Beneke's idea he will find an answer to most of the questions he asks me in his letter in THE LANCET of Dec. 12th, 1903, p. 1688. This idea, I have just said, received marked development from Bouchard; the views of the author are contained in his masterly work entitled "Maladies par Ralentissement de la Nutrition." Robin, in his first thesis, making an exhaustive study of the urine in typhoid fever, introduced the method of calculating the intensity of nutrition by means of the urinary co-efficient of oxidation.[1] A large number of analyses made by Gautrelet, Huguet, Richard, Vieillard and others, either independently or under the direction of Bouchard and Robin, led to the definite conclusion that this co-efficient was invariably low (actually or virtually) in the diseases designated by Bouchard as due to slow metabolism and that a fairly constant figure (84 per cent.) could be established for normal nutrition. But how were those cases to be interpreted, and they were present in a certain proportion, when the co-efficient of oxidation was persistently high? Obviously by invoking the factor of accelerated nutrition. Such cases included the subjects of the pretuberculous diathesis, those in possession of the same disease, and those showing a marked liability to infection in general.

Here then we had a large number of pathological processes explained by an extremely simple bio-mechanical theory. About the same time, however, Lecarché published his well-known work on gout and attributed this disease to hyper-nutrition, itself the consequence of the hypo-alkalinity of the tissues, and later Robin detached diabetes from the category of diseases due to slow nutrition to place it in the opposite class. Could these conflicting views be conciliated? Here again the bio-chemist suggested a solution by investigating, as Gautier does in his "Chimie de la Cellule Vivante," the aerobic and anaerobic characters of cellular nutritional processes.

The latest practical outcome of Beneke's conception is the application by Robin and Binet to the products of pulmonary respiration of the theory involved in the co efficient of oxidation. I referred in the paper discussed by Mr. Clayton[2] to some of the highly interesting results arrived at by those writers. Since then I have used their apparatus in investigating the vicarious functions of the lung in cases of hepatic insufficiency, as in the case of alcoholics. I have found the expiratory carbonic dioxide increased in such conditions. May not this overwork of the lung, it may be asked, be a factor in inducing the tuberculous infection which is so frequent a termination of alcoholism?

I am, Sirs, yours faithfully,

Nice. A. W. GILCHRIST, M.D. Paris.

THE TREATMENT OF CERTAIN FORMS OF OBSTINATE CONSTIPATION BY ENTERO-COLOSTOMY.

To the Editors of THE LANCET.

SIRS,—I have been interested in your annotation on Mr W. Arbuthnot Lane's case and in Mr. C. B. Keetley's lette because I dealt with a somewhat similar case in September 1902. The patient was a widow, aged 38 years, who gave a history of an attack of "peritonitis" in childhood. Sh suffered severely from constipation, without any of the ordinary features of acute or chronic obstruction. Even with the use of aperients and enemata the bowels seldom acted more than once in from six to eight days, and towards the end of the period of constipation she was tormented with headaches severe enough to incapacitate her and which were only relieved when she had passed a motion composed of small hard masses of fæces, each piece of about the size of a small marble. In spite of treatment with drugs, diet, massage, electricity, exercises, &c., the constipation became more obstinate and the headache more persistent. Judging that the constipation was produced by adhesions and that the headaches were stercoral I decided to open the abdomen and to make an anastomosis between any convenient parts of the small and large intestine. The adhesions were apparently due to a former attack of appendicitis, for they were more dense in the right iliac fossa and involved the cæcum and many coils of the lower ileum. With some difficulty I was able to effect an anastomosis between the ileum above the adhesions and the lower part of the sigmoid flexure. The patient made a good recovery and both her constipation and her headaches have been cured.

Mr. Keetley's *a priori* consideration that inconvenience might be caused by the fluid contents of the small intestine entering the rectum has not been borne out in this case, for the motions passed are solid and well formed. In this case it would, as Mr. Keetley suggests, have been better to do an end-to side rather than a lateral anastomosis, for my patient from time to time suffers pain and distension in the regions of the transverse and descending colon, and at such times fæcal masses can be felt there through the abdominal wall. It may become necessary to close the ileum below the anastomotic opening. I can see no reason why such an operation should not be performed for cases of constipation such as Mr. Keetley describes, and I quite agree with the advisability of making the anastomosis outside the abdomen if possible. My excuse for taking up your valuable space is the experience afforded by an actual case on two points raised by Mr. Keetley.—I am, Sirs, yours faithfully,

Salisbury, Dec. 28th, 1903. GILBERT KEMPE.

To the Editors of THE LANCET.

SIRS,—If Mr. C. Mansell Moullin will do me the honour of glancing through the short paper published under the title of "An Effectual Means of Dealing with the Conditions of Chronic Obstruction of the Large Bowel resulting from the Adhesions which Develop in Consequence of Chronic Constipation" in THE LANCET of Jan 2nd, p. 19 (which also contains his letter), he will see that the apparently rare and somewhat obscure case of atony of the large bowel on which he operated so successfully is neither similar in its causation nor in its pathology to the comparatively common and simple definite condition of mechanical obstruction described by me. I am, Sirs, yours faithfully,

Cavendish-square, W., Jan. 2nd, 1904. W. ARBUTHNOT LANE.

A PATHOLOGICAL CURIOSITY.

To the Editors of THE LANCET.

SIRS,—May I bring to the notice of the many readers of THE LANCET an interesting fact which was disclosed at a necropsy at the French Hospital a short time ago. On examining the kidneys it was found that the subject possessed three, two on the left side and one on the right. The two on the left side were fused together, one being on top of the other, and externally showed two ureters springing separately from two distinct pelves and continuing separately along their whole length, opening into the bladder by two distinct openings, one being about a quarter of an inch above the other. On section there was a distinct demarcation of the two kidneys, which was not visible from the exterior. All three kidneys were normal in appearance and had no connexion with the cause of death. I should be glad to know whether this has often been found.

---

[1] The ratio between the total nitrogen and the nitrogen of urea; this ratio is also called "rapport urologique."

[2] THE LANCET, Nov. 29th, 1902, p. 1456.

I am, Sirs, yours faithfully,
JEHAN M. BARLET,
Resident Medical Officer to the Hôpital et Dispensaire
Français, Shaftesbury-avenue, London, W.C.
Jan. 3rd, 1904.

*** A supernumerary kidney is very rarely met with. It is regarded as an extreme instance of segmentation of the kidney of one side. In its most typical form it lies in serial order with the kidney of its own side but is entirely separated. It is provided then with its own vessels and its own duct. The duct may fuse with that of the other kidney or remain separate as in the case quoted by our correspondent. Kidneys with two pelves are possibly less marked instances of the same abnormality. Even in these the ureters usually fuse so that it is rare to find two ureters entering the urinary bladder on the same side. Our correspondent will find references to the condition in Rayer's work (Traité des Maladies des Reins, 1840) and also in Newman's paper on Malformations of the Kidney (Transactions of the Clinical Society, vol. xxxi.).—ED. L.

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—In affirming that I have in any way denied that the spiratory muscles are the chief agents in maintaining and gmenting pulmonary suction Dr. Harry Campbell is making entirely gratuitous assumption. How could anyone doubt e normal function of these muscles, albeit Dr. Campbell akes it appear as though he had expressly discovered it. hat I have maintained all along is that elastic recoil of the oracic wall is an important factor and that the inspiratory uscles in normal breathing contribute to pulmonary suction a different manner relatively to the lungs than they do when almonary tension is abolished, as in excessive emphysema in the initial stretching of the child's lung. In the latter ase Dr. Campbell is, to say the least, unguarded in labeling y statement as "untrue," as what I referred to was e stretching of the lung by the inflation of the collapsed veoli which occurs before the actual stretching of the astic fibres. I also oppose Dr. Campbell's oft repeated and ovel plea that the inspiratory mucles are "ever busy" and moment by moment" keeping up the pulmonary tension, r the very obvious reason that these muscles are not acting uring expiration, and as expiration lasts longer than inpiration the inspiratory muscles instead of being "ever busy oment by moment" are in fact idle the greater part of the me.

It is instructive to note Dr. Campbell's attitude in gard to passive recoil and the extension of the pleural argins of the lungs. In the former case he carefully vades reference to the particular words to which I ave several times taken exception, and in the latter ase he adopts what, without any discourtesy, may be ermed the subterfuge that the "confines" of the pleuræ ay be interpreted in his previous letter, not as representing heir normal boundaries (as was undoubtedly implied therein) ut as including any space into which the pleuræ can be tretched. In directing attention to the fact that in addiion to the complemental pleural spaces there existed what may term an extra reserve space, it was merely to show hat there was no physical impossibility, as supposed by r. Campbell, in the lungs being stretched beyond the leural boundaries. But as regards a displacement of the wer borders of the lung in excess of that produced by a eep inspiration, it is by no means necessary to suppose hat this extra reserve space is utilised when the lung eflex is induced, because the fact is that by ordinary deep

be filled by the
pleural space if
kes the strongest
nspirations he can. It may here be added that in the disension which follows on the induction of the lung reflex phenomenon after passive recoil of the chest has done its part the diaphragm (specially) and the other inspiratory muscles contract in obedience to the requirements of the pulmonary relaxation. I think it will be seen from the foregoing considerations that the "impossible position" of Dr. Campbell is once more disposed of.

Hitherto not a few of Dr. Campbell's criticisms have been ingenious and serviceable in the elucidation of the lung reflex phenomena, but certainly his comments on the reflex of contraction are peculiarly unfortunate. He believes that sudden bronchial contractions in a limited area of lung will have the effect of distending the pertaining alveoli and actually cites as analogous the case of the asthmatic paroxysm. If Dr. Campbell will take the trouble of observing the most ordinary laboratory experiment on vagal stimulation inducing bronchiolar contraction he will see that the result is an almost immediate diminution in lung volume. It is only when the bronchiolar contraction is persistent that the air gradually gets imprisoned and inflates the alveoli to distension. In this connexion it is interesting to note that recently Aufrecht[1] announced that by means of the Biondi-Heidenhain stain he has succeeded in demonstrating a longitudinal layer of muscular fibres in the bronchial tubes, to the vermicular contraction of which the expulsion of air and secretion is largely due. I should consider it likely that in the circumscribed lung contraction which succeeds to focal concussion of the thorax such function of the longitudinal fibres is not rendered altogether invalid, whereas in the asthmatic paroxysm the retention and accumulation of air are more fully explained by the persistent local contractions of the circular fibres throwing the longitudinal fibres out of action. In regard to the new consideration introduced by Dr. Campbell at the end of his letter, I have not as yet heard of its being mooted either by Dr. Abrams or his "disciples" that the margins of reflexly expanded portions of lung move more extensively than normal. Reasoning from what takes place in emphysematous conditions generally I should have imagined the very opposite to be the case.

I am, Sirs, yours faithfully,
Henrietta-street, W., Jan. 4th, 1904. A. G. AULD.

LONDON HOSPITALS AND CENTRAL CONTROL.

To the Editors of THE LANCET.

SIRS,—The question of the possibility of submitting the London hospitals to some form of central control, organised

diture and of economising
casually into the field of
ngaged in procuring funds
for their support, and has again been brought into prominence by a letter from a manifestly well-informed correspondent of the *Times*, which appeared in that journal on Dec. 26th and which takes a somewhat alarmist view of the future of hospital finance. The writer of the letter believes that unless the now constantly increasing demands of hospitals can be systematised and checked by some central board or other body constructed for the purpose, and possessing the confidence of the public, the patience of donors will be exhausted, and that the institutions themselves must either cease to discharge their functions or must become dependent upon the rates and subject to municipal administration. In the discussion of this subject members of the medical profession have hitherto taken only a small part, but it is so intimately connected both with professional education and with general professional welfare that it seems to be quite worthy of all the attention which can be bestowed upon it. It is easy to understand that physicians and surgeons intent upon their own work, and sufficiently burdened by their own responsibilities, may hesitate to approach those which seem to belong more properly to treasurers and committees, but the connexion between the two is so close as to be practically inseparable, and the financial errors of a committee can never be without influence upon the government of the wards or upon the treatment of the sick. On this ground, and by reason of the enormous importance of the hospital system to the community, it seems eminently desirable that the profession should contribute its special knowledge towards the solution of problems which, at the present time, appear to weigh chiefly upon the shoulders of non-medical philanthropists,

---

[1] Deutsche Archiv für Klinische Medicin, Band lxvii., H. 5 and 6.

and to be on the verge of reducing many members of that useful and estimable class to the borders of despair.

When viewed with reference to the only two questions of paramount importance, the advancement of medical science and the treatment of the sick poor, it is impossible to deny that the London hospital system, regarded as a whole, affords an extraordinary example of misdirected and overlapping energy and of obsolete arrangements. The localisation of the great general hospitals bears no discoverable relation to that of the patients for whose benefit they are supposed to exist and to be maintained, while the smaller ones are scattered as aimlessly as if their seeds had been sown by birds or by the wind. A large proportion of the numerous special hospitals have arisen at the bidding of practitioners desirous to obtain some advantage from them, and were originally planted wherever a house not too far from the residence of the founder could be obtained, or wherever a local philanthropist could be induced to identify himself with the rising institution and to take its fortunes under his wing. There is probably not one London practitioner in a hundred who could say offhand how many hospitals for any particular specialty are in existence within a mile of his residence, or by what physicians and surgeons they are officered, and there are unquestionably many of such hospitals which are not regarded as sources of any especial light and leading with reference to the departments of practice which they profess to make their own. The most that can be said in favour of them, in a general way, is that they furnish the members of their staffs with opportunities of operative and other practice which may eventually be turned to the advantage of patients outside their walls, and that for various reasons they obtain support from donors who might not be reached by the appeals of more important charities, and who, if they did not give to these, might possibly not give at all. To their discredit must be placed the enormous evil of an unnecessary overlapping of appeals and of an unnecessary multiplication of establishments and of paid officials, all requiring the diversion to other purposes of money which ought to be devoted to the treatment of the sick, and this to such an extent that in all probability a central board free to reorganise at its pleasure, to suppress, to establish, to remove, and to amalgamate, would be able to carry on a complete hospital system for London at far less expense than is now required for an incomplete one. Is it quite beyond hope that some such board may ultimately be obtained?

I am, Sirs, yours faithfully,
Hospital Surgeon.

THE NEW REGULATIONS FOR THE INDIAN MEDICAL SERVICE.

To the Editors of The Lancet.

Sirs,—May I trouble you with a few lines relative to the letter of "Veteran" in your issue of Nov. 14th last, p. 1396? His penultimate paragraph may if not corrected raise false hopes in the breasts of intending candidates for the civil branch of the Indian Medical Service. It is true that before the introduction of the new rates of pay the pay of a second-class civil surgeoncy was Rs. 50 per mensem less than that of an officer in permanent charge of a regiment, yet this is not now the case, as I know from experience. The pay remains the same as before and is consequently now Rs. 100 a month less than that for permanent charge of a native regiment, so that his remarks regarding the chance of private practice should be carefully noted by all intending candidates. It is very rare for any civil surgeon of a second-class station to make anything approaching this sum (Rs. 100) in private practice; 30 to 50 rupees a month would give a fair average of the takings from private practice.

Comparing the pay of the Royal Army Medical Corps and the pay of the Indian Medical Service (new rates) the advantage is all in favour of the Royal Army Medical Corps, their pay being brought up by "charge allowance" to above that of the pay of corresponding ranks of the Indian Medical Service, and there is no increase of pay to compensate the Indian Medical Service for continual service in India and many other disadvantages. I could give many instances showing the inadequacy of the new memorandum but will not trespass on your space to do so; my object is to point out that the civil surgeon does not yet benefit by the revised rates, rather is his position relatively worse. We must, however, be thankful that a move has been made in a right direction, a move which inspires us to hope that the civil branch (the bait that attracts, or attracted, men to the Indian Medical Service) will shortly receive the much needed improvements.

I am, Sirs, yours faithfully,
S. I. M.

Spiral Formations in Relation to Walking, Swimming, and Flying.—A letter from Mr. Theodore A. Cook, whose name was freely introduced into Professor Bell Pettigrew's paper on this subject, was received too late for publication. It will appear in our next issue.

LIVERPOOL.

(From our own Correspondent.)

Sleeping Sickness in Liverpool.

Two cases of presumed sleeping sickness in the first stage sent by the authorities of the Congo Free State arrived at Liverpool on Dec. 28th, 1903. These cases have been sent to the Liverpool School of Tropical Medicine in order that a study of the disease may be made in England as well as in Africa. The change from tropical Africa to these northern latitudes has had a tonic effect on both natives; one of them who was in a weak condition when he left the Congo now shows much more vigour. The other patient has never shown any serious symptoms, and it is only the presence of the trypanosome in the blood which indicates that he has been attacked by the disease. Both are now under observation by Professor Ronald Ross, the director of the Liverpool School of Tropical Medicine.

Infectious Diseases in Liverpool: Question of Hospital Accommodation.

The medical officer of health (Dr. E. W. Hope) reported to the health committee of the city council on Dec. 31st last that there were one case of small-pox and 334 cases of scarlet fever under treatment in the corporation hospitals. In reply to Alderman W. Roberts who asked if there happened to be an increase of scarlet fever patients whether there would be hospital accommodation, Dr. Hope replied that the city was exceptionally free at present from all forms of infectious disease; indeed, it had not been so free within the past ten years. At present 474 patients were in hospital, but inasmuch as there were 900 beds, only about one-half of the hospital accommodation was in use, so that the state of things was very satisfactory.

Prevention of Malarial Fever.

At the monthly meeting of the Liverpool Chamber of Commerce held on Dec. 29th last a letter was read from the Glasgow corporation stating that as a result of the visit to that city of Professor Ross of the Liverpool School of Tropical Medicine it and other bodies in Glasgow had decided to join with the authorities of other towns to bring pressure to bear on the Government to take steps to investigate the ravages of malaria. Professor Ross said that all were agreed that the Government should move quickly. Manchester, Newcastle, and Sheffield were also prepared to join and the Liverpool School of Tropical Medicine proposed to draw up a plan of action to be taken after the return of Sir William MacGregor from Lagos.

Scholarship in Dermatological Research at the University of Liverpool.—Proposed New Lectureships.

Dr. George G. Stopford Taylor has offered to the medical faculty of the University of Liverpool a scholarship of the value of £100 a year for five years for the purpose of original research in the study of dermatology. The scholar who will be appointed will act as clinical assistant in the out-patient department of the Liverpool Skin Hospital and will also devote a portion of his time to research work at the Thompson-Yates laboratories. The offer awaits the sanction of the council of the University. The medical faculty has also recommended to the council the institution of two new clinical lectureships, one in dermatology and the other in laryngology.

Jan. 5th.

The Death of Professor Karl von Zittel.—The death is announced as having occurred at Munich Tuesday last of Professor Karl von Zittel, the palæontologist and author of a "Manual of Palæontology."

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Small pox Hospital.

THE hospital in which small-pox patients are at present isolated in Cardiff consists of corrugated iron structures which were erected many years ago upon land adjoining the permanent buildings provided for other infectious diseases. The site is on the outskirts of the town and is bounded on two sides by railways, so that it cannot be built up to very closely. The small-pox buildings have over and over again be [illegible] an outbreak of the di [illegible] initial case, but the [illegible] existing wards by mor [illegible] Government Board, however, refuses to sanction a loan for the erection of a small-pox hospital in proximity to the general isolation hospital. There does not appear to have been at any time a transfer of infection from one institution to the other. In this connexion it is of interest to note that there is a well-equipped hospital on one of the islands in the Bristol Channel for the purpose of isolating cases of plague or cholera. This hospital, which has a crematorium attached to it, is for the use of the Cardiff, Newport, and Barry port sanitary authorities.

Housing in the Rhondda Valleys.

In 1902 the Rhondda urban district council promoted a Bill before Parliament, one of the objects of which was to provide a system of electric tramways within its district. A strong argument in favour of the measure, and one which evidently had some weight with the Parliamentary committees before which the preamble of the Bill was proved, was the relief which the proposed tramways would give to overcrowded areas - It was stated in evidence that in certain districts surrounding collieries which were in full work there was a dearth of houses, so that two, and even three, families often occupied one house, whereas in other parts only a few miles distant empty houses were frequently found and that, as the overcrowded and less crowded areas were not constant but varied in accordance with the activity of the particular colliery concerned, a complete system of tramways would enable the colliers to reach their work, even though they lived at some distance from it. The district council has- not yet provided the tramways which it considered were so urgently needed in 1902, but the Taff Vale Railway Company has instituted a service of motor-cars which may do a great deal to lessen the overcrowding complained of. The cars will run upon the existing lines of railway which traverse both the Rhondda valleys but will stop to pick up and to set down passengers at many fixed points between the regular stations. Each car is self-contained, resting on four pairs of bogey wheels, and is worked by a small steam motor in the front. There is accommodation for 16 first class and 40 third-class passengers, each compartment opening on to a central platform, from which steps can be let down when the car stops elsewhere than at a station. The gradients in some parts of the line are heavy but they are easily taken by the cars and full speed can be attained very quickly.

Remuneration of Colliery Surgeons.

An unsuccessful attempt has been made to alter the arrangements existing between the colliery surgeon and the managers of the Powell Dyffryn collieries and ironworks at New Tredegar (Mon.). For many years past a poundage has been deducted from the workmen's wages and handed to the surgeon but a few men desired to have the deductions handed to a committee of themselves and to pay a fixed salary to a surgeon or surgeons and to defray the cost of the practice. A representative meeting of the men was held on Dec. 14th, 1903, when the whole question was discussed and eventually 67 voted for the continuance of the present system and only 29 in favour of the proposed change.

Cleanliness of Milk-supplies.

A slight outbreak of milk-borne scarlet fever in Bristol was reported upon by the medical officer of health (Dr. D. S. Davies) on Dec. 15th, 1903, and in the course of his report Dr. Davies said that the outbreak helped to emphasise the repeated [illegible] dirty habit of [illegible] ooked milk. Tl [illegible] o discussed at a meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health, held at Exeter on Dec. 17th, when Dr. W. H. Symons of Bath suggested that evidence of fæcal matter and other deleterious substances in milk should be considered as adulteration and should be punishable by fine or imprisonment.

Hospital Sunday Fund at Plymouth.

Oct. 25th was observed in Plymouth as Hospital Sunday when the collections at the various places of worship amounted to £808, which sum has now been handed to the committee of the South Devon and East Cornwall Hospital, Plymouth. The Sunday schools collection in aid of the children's ward of this hospital during 1903 amounted to over £62.

The Vacation and Measles in Glasgow.

THE Christmas and New Year vacation of the universities and the extramural schools of medicine in Glasgow is now passed, the classes having resumed work on Jan. 5th. The public schools in the city, however, on the recommendation of the medical officer of health of the city of Glasgow (Dr. A. K. Chalmers), have received a more extended holiday than usual—a period of 18 days—in the hope that this will have some influence in staying the progress of an epidemic of measles which has been affecting school children for some time.

Small pox in Glasgow.

This disease is still on the increase. On Jan. 1st nine cases were admitted to Belvidere Hospital, making 184 cases under treatment on that day. The total number of cases discovered since the beginning of the epidemic is 306, of which 24 have died. The public, however, does not appear to be much disturbed and its apathy has increased the difficulties of the sanitary authorities in obtaining more general revaccination. Experience shows that this only becomes possible in a community like Glasgow when the epidemic assumes alarming proportions and a certain degree of scare is produced urging people to a course of action which has been long pressed on them and at a period when more successful results would have followed. The efforts, nevertheless, of the local authorities in this and other directions in staying the progress of the disease are untiring.

The Western Infirmary, Glasgow.

A feature of this season of the year has been the annual gatherings in the different charitable institutions of the city. Those which have naturally attracted most attention were in connexion with the three principal infirmaries—the Western Infirmary, the Royal Infirmary, and the Victoria Infirmary. At the Western Infirmary on Dec. 29th, 1903, the managers and friends of the institution met the staff in the large conservatory where the formal part of the proceedings took place. Here the chairman of the committee of management (Mr. J. H. Dickson) in a short address referred to the encouraging support which the public was giving to them in their efforts to extend the infirmary. The new dispensary, which will be one of the finest in the kingdom, is fast approaching completion and the managers trust that the subscriptions which at present are being obtained will enable them to extend the hospital by the erection of a new wing. This is, indeed, urgently required. The hospital is constantly overcrowded and at present there are over 300 cases awaiting admission. One reason for the demand for more accommodation is the increase of industries in the neighbourhood and the consequent larger number of accident cases which require immediate admission. There is need for three times the accommodation for these cases that was required a few years ago.

The Royal Infirmary, Glasgow.

The gathering at this institution took place on New Year's Day and the Lord Provost (Sir John Ure Primrose) presided. Much interest was taken in the statement of the chairman of the house committee (Mr. J. D. Hedderwick) to the effect that the managers were beginning to see their way clear for making a start in the rebuilding of the old institution. No pains have been spared to make the scheme perfect. Plans have been adopted by the executive committee of subscribers and by the managers which have been amended to some extent at the instigation of the staff. One condition agreed upon has been that the outside walls of the present building shall remain, but it is believed that the reconstruction can be accomplished perfectly even under this condition.

The Victoria Infirmary, Glasgow.

A similar gathering took place at the Victoria Infirmary, at which the treasurer made the pleasing announcement that a New Year's gift had come in the form of a cheque for £1250 from Mr. William Buchanan, of Glasgow, for the endowment of a bed in one of the wards.

(From our own Correspondent.)

Queen's College, Belfast.

The council and corporate body of the Queen's College, Belfast, have passed a series of resolutions calling upon the Government to grant to the College an amount of financial assistance in accordance with its requirements. It is pointed out that the existing arrangements are absolutely inadequate and the fact that the public have subscribed generously to an equipment fund constitutes a still further argument for Government aid. The only reason for the continual postponement of any measure providing for the requisite equipment of the College must be the difficulty of finding a practicable scheme for settling the general university question, but to insist that this difficulty should be permitted to stand in the way of the development of higher education in Belfast would be unjust to those who have acted in response to the Treasury's request for evidence of local support. Moreover, postponement for such a reason would introduce conditions which have not in any way been created by the College and over which it has no control.

Health of Belfast.

At a meeting of the corporation of the city of Belfast held on Jan. 1st an important discussion took place in reference to the treatment of consumption. The medical officer of health, Dr. H. Whitaker, recommended (1) that suitable open-air spaces should be provided in the city for those suffering from this disease; (2) that a properly equipped sanatorium for 100 patients should be provided; and (3) that phthisis should be made a notifiable disease. The adoption of these suggestions was proposed and seconded by the chairman and vice-chairman of the public health committee, but an amendment to pass the minutes of the public health committee and to refer further discussion to the council in committee for consideration and report was carried; in other words, to shelve the whole question again. It is indeed deplorable to have to state it, but it is nevertheless the fact, that in questions affecting public health there is in the corporation of Belfast really no healthy opinion. They "care nothing for such things." Attention may be drawn to the fact that the improvement committee has actually recommended that a plan should be approved for several houses with no back passages on the extraordinary ground that "the committee find it impracticable to procure a back passage to the houses." Strong objections were taken to the retrograde proposals, some of the councillors protesting against the committee attempting to overrule the objection of the surveyor, and ultimately this matter was also referred for consideration.

Retirement of the Chairman of the Public Health Committee of Belfast.

Alderman J. Graham, M.D.R.U.I., chairman of the public health committee of Belfast, is about to retire from this office. He moved for the last time on Jan 1st the minutes of the committee of which for a lengthened time he has been chairman. He referred with satisfaction to the comparatively good state of the health of Belfast, the death-rate for the year being only 19 8—the lowest on record. It will be gathered from the previous paragraph that Dr. Graham's successor will not find his task a grateful one, for he will have to deal, with no real support from the rest of the corporation, with such questions as the milk-supply, the consumption problem, the infectious diseases hospital, and the drainage of the city. Your readers know how much despite a comparatively low death-rate, remains to be done for the public health of Belfast

Rainfall in Belfast in 1903.

At Queen's College, Belfast, 42·33 inches of rain fe
compared with the average of 33·55 inches for 38 years.
Springfield, near Belfast, it was 47·23 inches, or 6 35 a
the average for 27 years (40·88), and at the Linen
Library, in the centre of the city, it was 40·78, five in
more than the total of 1902 The rain-gauge at the Col
is 68 feet, at the Linen-hall Library 17 feet, and at Sp
field 150 feet above sea-level. The fall was greater in
when it was 44·51 inches, but for sheer persistent rainfal
year 1903 makes a record in Belfast, as rain fell actuall
269 days, the only years approaching it being 1877
1900, with 216 and 212 days respectively. Not a single
in October was without rain, 6 82 inches at Queen's Co
and 7·30 at Springfield falling, in both cases being pr
cally double the average. In Ulster, outside Belfast,
rainfall has also been remarkably high; and at Seaf
co. Down, the register was 48·69 inches for the
against 42·68 for 1902, or the heaviest for many years
Rain fell on 244 days, as against 201 in 1902; whil
October the gauge registered 7·43 inches. Last
exceeded the average at this place for the past 18 yea
over ten inches.

Lumbar Puncture in Diseases of the Ear.

At the meeting of the Academy of Medicine hel
Dec. 29th, 1903, M. Babinski announced that he had tre
a certain number of disorders of hearing by puncture of
spinal canal. It is found that there is a relation bet
the pressure of the cerebro-spinal fluid and the pres
of the fluid contained in the labyrinth of the
Instances of vertigo have been remarkably bene
(21 recoveries in 32 cases). Tinnitus was some
less obviously influenced (30 recoveries or instance
improvement in 90 cases). Deafness was generally resis
especially when unaccompanied by tinnitus or vertigo.
this class of cases there were only 13 which were impr
in a total of 100, but some of the successes which
obtained were remarkable. For instance, after lu
puncture a lady who had been deaf for ten years was
to hear whispering at a distance of six feet. The treat
seemed to be free from inconveniences beyond
temporary malaise.

The Lazaret at Frioul.

At the same meeting of the Academy M. Josias read
conclusions of the report which he had communicated to
Academy at its meeting held on Dec. 8th, 1903, relati
the steps required to be taken with respect to the lazar
Frioul. The lazaret ought to be fitted up with more regar
health and comfort; it ought to include an infirmary
separate rooms for ordinary patients and a hospital
patients suffering from virulent epidemic diseases, suc
plague, cholera, yellow fever, and the like; and it o
to be provided with every available means for the
vention and treatment of such ailments. The meas
for the disinfection of a ship before unloading
for the destruction of rats, ordered by the recent de
of Sept. 21st, 1903, should be applied effectively. T
conclusions gave rise to an interesting discussion.
Monod, director of the public health service and
the Assistance Publique at the Ministry of the Inte
was the first to speak. He said that the administra
agreed with the opinion of M. Josias that the old lazare
the Ile Ratoneau was in a deplorable state, and the rebu
ing of it has always been first on the list of refo
to be undertaken at Frioul. Inadequate grants of mo
have been a cause of delays and difficulties but
deficiency has been provided for in the Budget of 1904
recent conference held in Paris has modified the conclus
arrived at by the Venice conference by shortening the pe
of observation of suspected cases and by occasionally
pensing with processes of disinfection. But this relaxa
of quarantine precautions would have to be supplemented
a rigorous application of the law of 1902 which w
lead to the general hygienic improvement of Fra
One of the great difficulties in the organisation of
Frioul establishment consisted in this, that the buildi

which were too large in ordinary circumstances would be inevitably too small in the event of an epidemic M. Monod also maintained that the places ought to be furnished comfortably enough to prevent the persons detained there from making complaints. M. Vallin spoke in opposition to a view which has been held for the last two years—namely, that large sums would be required for the carrying out of the modifications proposed by the Academy. This, he said, was a mistake. In European ports severe epidemic diseases did not present themselves many at a time, so that it was unnecessary to provide accommodation for great numbers of persons. It might be sufficient to provide from 25 to 50 well-appointed places in the departments allotted to observation and treatment. The sanitary certificate would be of great use as soon as rigorous supervision was exercised, whereas at present it was a farce. It was also necessary to calm the fears of the people in the seaport towns in order to avoid the panics which were caused even now by reports of cases of plague. M. Brouardel pointed out that all the terms of a convention must be fulfilled by the contracting parties and that France was consequently bound to carry out the scheme adopted by the conference which had just been held in Paris. All the efforts of the representatives of France were required to secure some relaxation of quarantine precautions in opposition to the representatives of other nations who were [illegible] uarantine. There must be no [illegible] bservation of individuals in [illegible] a sanitary certificate and a large staff would be required in order that the observation might be effectual. It was necessary that every precaution should be taken and that the sanitary organisation should be complete, for if an accident unfortunately happened the Powers in favour of quarantine would use it as an argument against the comparatively mild system recommended by France. M. Laveran then drew attention to the necessity of destroying rats on shipboard. M. Roux said that these measures were of the greatest importance, but when the cargo on board was such as to require careful handling it might be damaged by the processes necessary for disinfecting the vessels and killing the rats. It was therefore advisable to make the following addition to the paragraph authorising disinfection previously to unloading: "Except in certain special cases in which it—i.e., disinfection—may be carried out after unloading." Both this modification and the conclusions of the report of M. Josias were approved by the Academy.

(FROM OUR OWN CORRESPONDENT.)

Medical Academies.

THE scheme of the Government for creating medical [illegible] ant provincial towns apart from [illegible] exion with the great provincial [illegible] time a subject of discussion in the medical and lay press. The idea appeared to be somewhat obscure, as notwithstanding manifold appeals the Government did not think it advisable to give particulars as to the organisation and the object of the projected academies. It must be remembered that medical education has hitherto belonged almost exclusively to the universities, of which the medical faculties and their laboratories, clinics, &c., are an integral part. The system is therefore different from that which exists in England where medical study is partly carried on in the medical schools attached to the great hospitals. The plan to found academies would thus have been a fundamental reform if indeed they were destined to copy the English system of medical training. The intentions of the Government are, however, far from being so radical. I learn that it will be the object of the new academies to deal not with medical study in the strict sense of the word but principally with post-graduate study, with the training of specialists, and with the so-called practical year which according to the new [illegible] hospital of 1000 beds will be built in connexion with a medical academy. According to this Bill the medical academy will consist of five divisions: for surgery, for clinical medicine, for obstetrics, for hygiene and infectious diseases, and for pathological anatomy and forensic medicine. With the first two divisions subdivisions for the special branches for diseases of the eye, the ear, the skin, the nerves, and for children's diseases will be connected. The teachers of the academy, to whom the title of professor will be granted, are the chief physicians and surgeons of the hospital who are appointed by the municipal authorities but must be authorised by the Government. It is explained in the Bill that the academy will be charged with the instruction of specialists for the reason that a great many medical men have assumed the title of specialist without a proper special training and after having taken only a few courses of some weeks. In future only those will be recognised as specialists who have been trained in their special branch by academical teachers and who can produce certificates of competence. Another object of the academy is the arrangement of post-graduate courses free of charge for the medical men of the district, after the pattern of the courses and lectures of the Central Committee for Post-graduate Study in Berlin and other towns. Moreover, the academy will deal with the training of nurses, with popular lectures on first aid, and with general hygienic matters. The cost of the Düsseldorf new hospital will be 5 500,000 marks (£275,000) and several years will of course be required before the buildings are finished. Meanwhile the Government Medical Department will probably enter into negotiations with the municipal authorities of other large towns where the existing hospitals are suitable. The plans of the Government concerning Düsseldorf are only known by a paragraph in some lay journals and neither the medical press nor the medical profession has had an opportunity of expressing any opinions in this matter. Obviously some of the particulars are rather objectionable and will not fail to become an object of controversy, such for instance as the appointment of the hospital physicians and surgeons. Hitherto the municipal authorities were at liberty to make appointments at the hospital under their jurisdiction entirely at their own discretion. In the case of a medical academy connected with the hospital the Government will be entitled to interfere with the appointment of the medical staff which has to act also as the teaching body of the academy; also the exclusive right of training specialists will certainly be much discussed. Although certain anomalies in this respect unquestionably exist it is wrong to say that specialist training must be valueless unless guaranteed by certificates of an academy or a university. Many of our leading specialists have not acquired their knowledge at an official university clinic but as assistants to a senior private specialist or by studying abroad. Moreover, to prohibit medical men from calling themselves specialists would be accomplished only by altering the laws on medical qualification with the approval of the Imperial Parliament and not by a mere governmental decree. Concerning the practical year it would be impossible to let all the students go to an academy as the number of places would obviously be too few to receive there all the young men coming from the universities, even if some six or seven academies were established. Only a small number of them would be admitted to an academy, whilst the remainder would have to go to other hospitals not in connexion with an academy, so that from the beginning the profession would be divided into two classes, a first and a second.

The Frequency of Appendicitis in Germany.

It is generally believed that appendicitis has become much more frequent during the last few years than at any previous time. Opinions, however, differ as to the causes of the increase and in Germany it has been alleged that it might have some connexion with the use of enamelled cooking vessels. It is supposed that when the enamel gives way pieces may be mixed with the food and produce inflammation. This opinion is contradicted by *Dr. Villaret*, surgeon-general at Posen, who denies that appendicitis has at all increased. He explains that the alleged increase is due to improvement in diagnosis, as many cases which formerly were registered as peritonitis and gastric and hepatic diseases are now registered as appendicitis. He quotes from the excellent statistical tables of the German army, comparing the numbers for the periods 1873–74, 1885–86, and 1900–01, and states that whilst appendicitis has increased by 70 per cent., hepatic diseases

---

[1] THE LANCET, June 7th, 1902, p. 1650.

have decreased by 64·2 per cent., peritonitis by 70·2 per cent., and gastric diseases by 79·9 per cent. These four groups of diseases in 1873–74 attacked 4·79 men in every 1000, but in 1900–01 they attacked only 2·66 men in every 1000, so that in the aggregate they have decreased by 44·5 per cent. The alleged increase of appendicitis is thus only an apparent one.

Jan. 5th.

SWITZERLAND.

(From our own Correspondent.)

Medical Societies and Medical Defence in Zürich.

In Zürich there are two medical societies, the older one of which is called the Medical Society and was founded half a century ago; it has 130 members in all, the total number of medical men in Zürich being 162. Ten years ago a few members took the view that the old medical society, although excellent in a scientific respect, nevertheless neglected the practical interests of the profession and they consequently founded the Society of Medical Practitioners, which now counts 45 members, the majority of whom are members both of the old and the new society. The younger society has done good work, not only in its scientific meetings, where lectures on practical subjects and demonstrations are a feature, but also in those meetings where the material interests of the profession had to be considered. Hospital abuse, cash practice, and fees paid by insurance companies were among the subjects which have been discussed and committees were appointed the labours of which have been successful in different directions. Six months ago a Society for Medical Defence was formed for the purpose of providing its members with legal assistance and also for the collection of unpaid accounts in as unobtrusive a manner as possible. The Swiss laws do not protect the medical practitioner even as well as the English law does and abuse is rife everywhere. The Society for Medical Defence had not long to wait before its services were in request. A large socialistic workmen's union sent circulars to a number of medical practitioners inviting them to become medical officers of the union in question and in these circulars there was a paragraph the meaning of which was that no distinction would be made between medical practitioners and persons who had obtained a diploma from a physical health society. The Medical Defence Society immediately called a meeting of all the medical men in Zürich to protest against this paragraph and obtained from 160 of them—i.e., from all but two—a verbal or written consent to a request for the cancelling of this paragraph. A committee of 12 medical men was appointed to carry on negotiations with the workmen's club and to settle terms and now an agreement has been made conformable with the requirements of professional ethics. This success, due to an almost unexpected amount of unity among the medical men, is of all the more import, for a public vote will soon be taken on the question whether members of "physical health societies" are to be allowed to practise "non-medicinally," as they have carefully worded their petition, in the canton of Zürich.

Zurich, Jan. 1st.

EGYPT.

(From our own Correspondent.)

The Egyptian Lunatic Asylum.

Dr. J. Warnock's annual report[1] on the only hospital for the insane in Egypt has just been published. A second hospital or greatly increased accommodation in the present one is urgently necessary, for in order to keep down the numbers at all the Government is obliged to discharge all lunatics who are not absolutely dangerous and no case can be admitted unless it is certified as being dangerous, a point difficult to determine in a country where very few of the native medical men are trained in mental diseases and where fear of responsibility and sympathy with the lunatic are guiding influences. The public, as in other countries, obviously requires protection from discharged lunatics and many of the discharged but insane patients have no difficulty in remarrying and begetting children whom they are unable to support and to whom their father's insanity may be transmitted. The customs regulating marriage and divorce are so easy that marriage is often resorted to by the natives as a method of trying to cure the early symptoms of insanity. As an example of the need of protection required by the lunatic himself, a case is mentioned of a woman suffering from acute mania, who was admitted to the asylum with a compound fracture of the bones of the forearm, gangrene of the arm, general septicæmia, and numerous bruises and wounds of the head; these lesions had existed for some days, during which time the patient had been wandering about the streets. Among the year's improvements are electric light which has been installed and which is an immense improvement on the former petroleum lamps, for it is now possible to keep many of the dormitories almost in darkness at night and thus quiet and sleep are promoted. It is satisfactory to note that mechanical restraint is practically never used except in surgical cases, the treatment depending entirely on the vigilance of the attendants and the isolation of excited patients when necessary. Many readers will remember that all violent patients in this asylum were heavily chained to the walls less than 20 years ago. The number of paying patients is gradually increasing every year and during 1902 the relatives of the better class lunatics contributed £1520 to the expenses of the asylum, so that after deducting all receipts the net cost per patient per annum is £21. Although the water bill for the year is as high as £214 there is an insufficient supply for baths, and the arrangements in case of fire are still far from ideal when it is remembered that nearly all the inmates love cigarette smoking. The area of the asylum grounds urgently requires extension, for the public can talk to the patients through some of the windows abutting on the roadway of the desert and it is to be hoped that some day a railway line for carrying stone from the desert hills will be removed to a distance greater than 20 yards from the asylum. Mats, baskets, and cloth are manufactured by the patients, but the necessity of discharging lunatics almost as soon as they are sufficiently tranquil to engage in an industry prevents much being done. It is, indeed, often difficult to find enough quiet patients to work in the kitchen, the bakery, and the laundry, for all the cleaning of the hospital is done by patients and they also undertake the care of the buffaloes for milk-supply, the sewage disposal, the distribution of food, and the gardening. The average number of resident patients was 488 and during the year 104 former cases were re-admitted. The total admissions included 133 cases of mania, 72 of hasheesh insanity, 31 of pellagrous insanity, and 14 of alcoholic insanity. General paralysis accounted for 15 patients, or 3·7 per cent. of the total admissions, and seven of them were known to have suffered previously from syphilis Ten of them were Egyptians, including two females, besides two Turkish women, two Italians, and one Austrian. Ten of the 67 deaths were caused by general paralysis tuberculosis and dysentery each accounting for seven There is no lunacy law in Egypt for criminals or others and there are several points which require to be settled, such as the liability of relatives for the cost of maintenance in the asylum and the procedure to enforce payment, the imposition of special penalties for the ill-usage of lunatics by their attendants, the duty of the local authorities to report cases of ill-usage of lunatics, the inspection of lunatics existing in charitable and religious establishments, and the means of preventing neglect and cruelty in such places. The greatest reform during the year has been the appointment of Dr. H. W. Dudgeon as deputy superintendent and he has already done much useful work. What is now wanted is money to provide for an English storekeeper or steward and for an English matron to control the female side.

Dec. 30th, 1903.

NEW YORK.

(From our own Correspondent.)

Alleged Discovery of the Cause of Scarlet Fever.

Before the Boston Medical Society on Dec. 15th Dr. Frank B. Mallory, associate professor of pathology at Harvard University, described a microbe which he believes to be the cause of scarlet fever. It is not a bacterium but a protozoon found in the epithelial cells of the skin and tongue and in the superficial lymph vessels and spaces of the corium. The protozoon is said in some respects to resemble that of malarial fever but is larger. It is found in two forms—either as a radiated rosette or in a granular form with knotted reticulum. Dr. Mallory does not claim that this organism is definitely proved to be the cause of scarlet fever but he thinks that further research will substantiate the validity of his conclusions.

[1] A short notice of this report has already appeared in our columns.

New York State Anti-Sanatorium Bill.

A Bill termed the Goodsell-Bedell Bill was enacted at the last session of the New York Legislature and signed by the governor of the State. This Bill to all intents and purposes prohibits the erection of sanatoriums for consumptives by any city in New York State outside its own limits. From the first medical men were strongly opposed to the passing of such a Bill and protests to this effect were sent to the governor. This action, however, was of no avail and the Bill became law. The New York Society of Medical Jurisprudence met recently and motions deprecating the course taken by the governor and legislature were introduced by Dr. S. A. Knopf. The motions requested the governor to repeal the law, "which, if it should remain on the statute books and be enforced, would involve the loss of thousands of lives and increase the spread of tuberculosis within the crowded districts of the cities and towns to an alarming degree." He declared that the Bill paid undue attention to property interests with no regard for the consumptives of the State.

Anti-Mosquito Convention in New York City.

A convention to devise the most efficient means of fighting mosquitoes has recently been held in New York city. The governor of New Jersey presided and Mr. Robert W. De Forest, of the Charity Organisation Society and president of the Tenement House Commission, was chosen permanent president. Motions were adopted recommending that a provisional committee be appointed by the convention to consider the formation of a central organisation of national character with which local bodies might coöperate in conducting a crusade against mosquitoes.

Antiseptic and Germicidal Properties of Glycerine.

Dr. M. J. R[illegible] the United [illegible] has for som[illegible] antiseptic and germicidal properties of glycerine. Glycerine be found to possess a distinct though exceedingly feeble germicidal action. His opinion was that it cannot be depended upon to purify vaccine lymph or other organic matter containing spores of tetanus.

The Abolition of the Canteen in the United States Army.

Army officers are almost unanimous in the opinion that doing away with the canteen has been productive of much vil. At the meeting of the American Public Health Association held in Washington in October Dr. George McKober read the report of the committee on the canteen n armies. In it was sketched the history of the system ince its institution at Vancouver Barracks in 1880. The anteen was officially recognised in the United States Army n February, 1889. Only light wines and beer were allowed o be consumed. The committee finally stated its belief hat the sale of alcoholic liquor in canteens under rational gulations, rather than its total prohibition, will best serve e interests of temperance.

Dec. 26th, 1903.

THE FURIOUS DRIVING OF MOTOR-CARS.—Several ses have occurred during the first week of the new Act of otor-cars being driven in London in such a way as to danger the public. One defendant, in answer to a mmons, pleaded with some success that he did not ow the pace at which he was travelling In another se the summons was dismissed, as there was some ubt about the police evidence, although in the magiste's opinion a technical offence had been committed. ere are, it is said, many motor-cars on the roads which are t licensed and numbered in accordance with the Act, the chinery of the Act having proved unequal to cope with e demands put on it. If this be so it behoves owners of tor-cars to be doubly cautious in their procedure; ignorce must not be regarded as an adequate excuse and the petrator of technical offences must expect to be punished, wever guiltless he may have been of wanton carelessness. e public must be protected.

Obituary.

JOHN KNOWSLEY THORNTON, M.B., C.M. EDIN.,

CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN, MARYLEBONE-ROAD, LONDON, N.W.

John Knowsley Thornton, who died on Jan. 3rd, was the son of the Rev. John Thornton, curate of All Saints, Northampton, afterwards headmaster of Kimbolton School and for 30 years vicar of Aston Abbots. Born on Jan. 15th, 1845, he was educated at Rossal and spent some years in teaching and clerical work before he began the study of medicine; hence, he was 26 years old when he graduated in the University of Edinburgh. After serving as Lister's house surgeon there, he practised for a short time at Ford, in Northumberland. In 1873 his friend Dr. William Thomson, now of Algiers, was compelled to leave London on account of his health, and through his introduction Mr. Thornton became surgeon to the Samaritan Free Hospital and also assistant to the late Sir Spencer Wells in his private work. Being an enthusiastic admirer of Lister he at once began to apply the principles of the antiseptic system to abdominal surgery and for nearly 20 years his methods were practically those taught by Lister before he left Edinburgh, even the spray being retained for a considerable period after it had been discarded as unnecessary by most surgeons. It was not long before Mr. Thornton established a reputation as one of the most successful operators of the day, especially in regard to ovariotomy and other operations requiring abdominal section, and he gradually became an authority on all [illegible] His writings on the surgery o[illegible] bladder, and the spleen wer[illegible] largely to advance knowledge of the surgical treatment of these organs. Unfortunately he was subject to frequent attacks of gout which began when he was only 18 years old and which frequently interrupted his work. Principally on this account he gave up hospital practice in 1891 though for some years later he carried on a large private practice. But gout and gouty complications of influenza laid him aside more and more frequently until in 1896 he had a severe and painful illness which stopped all work for more than six months, and in 1898 he retired.

Mr. Thornton's work was characterised by great thoroughness in detail and he also seemed to have an intuitive knowledge which was seldom at fault as to the nature of a patient's disease and the most suitable treatment. During an operation complications seemed only to stimulate him, and if there was a way out of a difficulty he was sure to find it. These characteristics gained for him the confidence of a large section of the profession and of the public and there can be little doubt that if his health had been good his practice would have been measured only by his own wishes.

In addition to his appointment at the Samaritan Hospital Mr. Thornton was surgeon to the Grosvenor Hospital for Women and the New Hospital for Women, and his practice did not leave him much time for literary work. The writings to which we have alluded took the form of communications to the *British Medical Journal* or our columns, or of articles in well-known compilations. For example, Mr. Thornton wrote the articles "Ovariotomy" and "Hysterectomy" in Heath's "Dictionary of Surgery," and the article "Hysterectomy" in Allbutt's "System of Medicine." He also contributed many papers to the Transactions of the Royal Medical and Chirurgical, Obstetrical, and Medical Societies, of which last body he served as president.

Since his retirement Mr. T[illegible] Hall, Cambridgeshire, one [illegible] care of his garden. His h[illegible] had been subject to attacks from his old enemy and during the greater part of last year he suffered much from peripheral neuritis which gradually exhausted his strength. Mr. Thornton married twice and leaves by his first wife a son and two daughters and a daughter by his second wife, a sister of Lord Windsor, who survives him.

SIR GEORGE THOMSON, K.C.B., M.B., C.M. ABERD.,

LATE SURGEON-COLONEL, I.M.S.

Surgeon-Colonel Sir George Thomson, K.C.B., late of the Indian Medical Service, died suddenly on Dec. 21st, 1903, at Leeford, Mowbray-road, Upper Norwood, aged 60 years. Sir

George Thomson was a native of Aberdeen and was a son of the late Mr. James Thomson. He was educated first at the old grammar school in Schoolhill and then at the grammar school known as "The Barn" in Old Aberdeen. He was a student of the University of Aberdeen and graduated M.B., C.M. in 1864. After leaving the University he entered the Indian Medical Service, in which he remained for 30 years, retiring at the end of that period. He became surgeon-major in 1877, brigade-surgeon in 1889, and deputy surgeon general (afterwards surgeon-colonel) in 1893. His record of service is a long and distinguished one. He was at one time civil surgeon in the Punjab and medical adviser to the Maharajah of Patiala and for several years he was principal medical officer of the Lahore military district. He served during the Afghan war of 1878–79, being mentioned in despatches and thanked by the Indian Government and receiving the medal. He was principal medical officer on the lines of communication of the Chitral expedition in 1895, for which he was created C.B. He was attached to the Malakand Field Force in 1897 and later in the year he served in the Tirah expedition as principal medical officer; for his valuable services in this expedition he was promoted to the rank of K.C.B. Sir George Thomson was married to a daughter of the late Mr. John Ferguson of Aberdeen. He leaves a widow and three sons. One of the brothers of the deceased, Major Thomson, is also in the Indian Medical Service.

CHARLES FREDERICK MOORE, M.D. GLASG., F.R.C.S. IREL., &C.

Dr. C. F. Moore died at his residence, 10, Upper Merrion-street, Dublin, on Christmas Day, 1903. Dr. Moore received his medical education in Dublin and in Glasgow. In 1842 he became a Licentiate in Midwifery of the Rotunda Hospital and in the following year a Licentiate of the Apothecaries' Hall of Ireland. A year later he qualified for the M.D. degree of the University of Glasgow and became a Licentiate of the Royal College of Surgeons in Ireland, receiving the Fellowship of that College in 1865. He received the Licence of the Apothecaries' Society of London in 1853. He was a Fellow of the Irish Royal Academy of Medicine and at one time acted as president of the State Medicine Section of that Academy. He had also held the post of president of the Dublin Sanitary Association and of vice-president of the British Association of Certifying Factory Surgeons. Of this latter association he was honorary secretary for Ireland. He was formerly an examiner in materia medica at Queen's University and of the Conjoint Board of the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Ireland. He contributed many articles of interest to the medical press.

ROBERT VICARS FLETCHER, F.R.C.S. IREL., L.R.C.P. IREL., &C.

Mr. R. V. Fletcher, the resident medical superintendent of the District Asylum, Ballinasloe, Galway, passed away on Dec. 17th, 1903, after a lingering illness following an attack of influenza which he contracted last winter. The deceased gentleman was born in the year 1840. He received his medical education at Dr. Steevens' Hospital, Dublin, and in 1865 became qualified. In the following year he was appointed assistant resident medical superintendent of the District Lunatic Asylum, Downpatrick, and in 1872 became resident medical superintendent of the District Lunatic Asylum, Waterford. In 1874 he was appointed resident medical superintendent of the District Asylum, Ballinasloe, which post he held until the time of his death. A little more than 12 years ago Mr. Fletcher, who had already considerably improved the organisation and administration of the asylum, induced the governors of the institution to add a new block of buildings containing a hospital and special ward for acute cases. The institution now contains 1100 beds and the position which it holds among similar institutions in Ireland is due in no small measure to the unremitting labours of its late superintendent.

ROBERT MANSFIELD TAGERT, M.D. GLASG., F.R.C.S. IREL.

Dr. R. M. Tagert died at his residence, 12, Vesey-place, Kingstown, on Dec. 27th. He took the degree of M.D. of the University of Glasgow in 1837 and in 1845 became F.R.C.S. Irel. He was formerly medical officer to the union workhouse and dispensary at Carrickmacross, also to Farney Baronial Fever and General Hospital. For the last few years he lived at Kingstown and was a well-known and much esteemed member of the township. He was considered to be the oldest medical man in the county of Dublin, for he had reached the patriarchal age of 91 years.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Kiréleff, *privat-docent* of midwifery and gynæcology in the St. Petersburg Military Medical Academy.—Dr Delotte, professor of internal pathology in the Limoges Medical School.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE. — *Berlin:* Dr. Paul Schultz, *privat-docent* of Physiology, has been granted the title of Professor.—*Bonn:* Dr. Schöndorff, *privat-docent* of Physiology, has been granted the title of Professor. —*Kieff:* Dr. Muratoff, Extraordinary Professor, has been promoted to the Ordinary Professorship of Midwifery and Gynæcology.—*Naples:* Dr. Giovanni Petella of Turin has been recognised as *privat docent* of Ophthalmology.—*Rio de Janeiro:* Dr. T. V. Pecegueiro do Amaral has been appointed Professor of Medical Chemistry in succession to the late Professor Ferreira dos Santos.—*St. Petersburg (Military Medical Academy):* Dr. B Petroff has been recognised as *privat docent* of Medicine.—*Vienna:* Dr. Florian Kratschmer, *privat docent* of Hygiene and of Medical Chemistry, has been granted the title of Professor. Dr. Dominik Pupovac has been recognised as *privat-docent* of Surgery and Dr. G. Alexander as *privat-docent* of Otology.

SOME NOVEL PATENTS.—An American inventor has patented a hen's nest which consists of "a receptacle for the hen and her eggs and a trough surrounding said receptacle, said trough being designed to hold an insecticide to prevent vermin from crawling into the nest and to catch the same." Another inventor has patented a mask intended to serve for prevention from drowning. The essential feature of this mask seems to consist in "openings covered with wire-netting or gauze, said openings being encompassed by short tubes upon the inside of said mask and said tubes having automatically closing valves." Descriptions and drawings of both these contrivances are to be found in the Official Gazette of the United States Patent Office issued on Dec. 22nd, 1903.

MIDLAND MEDICAL UNION.—The annual meeting of this union was held on Dec. 8th, 1903 at the Hotel Portland, Chesterfield. The retiring President, Dr. J. Goodwin Shea, J P., of Chesterfield, presided and was supported by Dr. George Booth, J P. (the President-elect), Mr. R. G. Allen, Mr. J H. Booth, Mr. A. Chawner, Dr. E. Wearne Clarke, Dr. W. Duncan, Mr. F. Edmunds, Dr E. B. Ffennell, Dr. J. A. Goodfellow, Dr. A. Green, Dr. E H. Houfton, Mr. B J. Lee, Dr. G. G. Macdonald, Mr J A Magee, Dr. W. M. Oldham, Mr. A. M Palmer, Mr. C. J Palmer, Mr W. W. Robinson, Mr A. W. Shea, Dr. G. T. Tate, Dr. S. Worthington, and others. Letters of regret for inability to attend were received from Dr. F. R Cassidi, Mr. J. H. Cox, Mr. G. W. Crookes, Mr. W. B. Crorkery, Dr. A. Fulton, Mr. E G Leary, Dr. F. R. Mutch, Dr. W. B. Ransom, and several others. A vote of thanks was passed to Dr. Goodwin Shea for the valuable services he had rendered to the work of the union during the three years he had held the office of President. The secretary read the report of the council setting out a summary of the year's work. Dr. Clarke proposed: "That the Midland Medical Union cordially approves and supports the claim which is at present being made for the establishment of a university in Sheffield." The motion was seconded by Dr. Goodwin Shea and carried unanimously. The meeting was followed by the annual dinner. After the Royal toasts had been proposed by the President (Dr. Booth) and loyally honoured, that of "The Midland Medical Union" was proposed by Mr. Simeon Snell who is one of the honorary secretaries of the committee for the establishment of a university in Sheffield. Mr. Snell in the course of his remarks referred at considerable length to the efforts which were being made in support of the movement and for raising funds for this object. Dr. Macdonald, the Vice-President, responded on behalf of the union. The toast of "The Guests" was proposed by Dr. Clarke and responded to by Dr. A. J. Hall.

LITERARY INTELLIGENCE.—"Proposed Sterilisation of Certain Mental and Physical Degenerates" is the title of a work by Dr. R. R. Rentoul which the Walter Scott Publishing Company have in the press.

THE ANGLO-AMERICAN FOOD COMPANY.—A vendor of meat extracts, trading under this title, was fined at Liverpool on Wednesday last £5 and 10 guineas costs for selling as extract of beef, labeled as consisting solely of the juice of the finest beef, matter containing half its weight of yeast extract.

BRISTOL DISPENSARY.—The annual report of the Bristol Dispensary for 1903, which has just been issued, states that during the year 10,874 new cases were treated. 582 midwifery cases were attended. The financial statement showed that the income amounted to £2329 and the expenditure to £3337; the deficiency was met by taking a sum of £1016 from the investment account.

VACCINATION EXPENDITUR[illegible] the Barnstaple (Devon) board of [illegible] it was reported that during the [illegible] previous to the passing of the recent Vaccination Act, 2653 vaccinations were performed in the Barnstaple union at a cost of £616, but that during the four years, 1900 to 1903, subsequent to the enforcement of the Act the vaccinations numbered 3004, the expenditure amounting to £1906.

THE ROYAL PORTSMOUTH AND GOSPORT HOSPITAL.—A searching inquiry was made on Monday afternoon last by the coroner for the borough of Portsmouth, Mr. T. A. Bramsdon, into the accuracy of certain allegations made by the relatives of a patient against the management of this institution. As a result it was conclusively found that the patient, who had died shortly after leaving the hospital at her own wish, had been treated correctly and humanely throughout.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. Alfred James Barker, M.D. St. And., late of Beaulieu Villas, Green-lanes, N., has recently retired from practice on account of advancing age. His friends and patients have taken occasion to present him with a farewell letter of address engraved in a beautiful illuminated album and accompanied with a purse. Dr. Barker has been in practice in the neighbourhood for between 40 and 50 years, and such a recognition of local esteem must give him much pleasure.—Mr. [illegible]. O. Shann, M.R.C.S. Eng., L.R.C.P. Edin., who recently retired from his position as medical officer of the York Union Workhouse, has been presented by the officials of that institution [illegible] jug and a silver fruit knife.—Mr [illegible] D. Edin., was on Dec. 22nd prese[illegible] an illuminated address as a token of esteem by his numerous friends and patients. Mrs. Morris was also presented with a tea service and Miss Morris with a gold demi-hunter watch. As a joint gift to Dr. Morris and his wife the people of Llanarthney presented them with a marble clock. Dr. Morris has left [illegible]antgaredig for Mardy, Glamorganshire, where he has accepted a medical appointment in connexion with the collieries.

DONATIONS AND BEQUESTS.—In addition to the gift of a site of 12 acres for the new buildings of King's College Hospital in South London from the Hon. W. F. D. [illegible]mith, M P., Messrs. W. H. Smith and Son have given a donation of £1000 towards the removal fund and promise a similar amount in 1905.—Lord Amherst has given to the [illegible]rth Eastern Hospital for Children £100 towards the deficit of £1100 carried over from 1903. This hospital has also received an anonymous donation of £500 towards the extension of the buildings, for the completion of which a sum of [illegible]4 000 is still required.—The Evelina Hospital for Sick Children has received from the "Zunz Bequest" £5000.—An anonymous donor has given £3000 towards the endowment fund of the Hospital for Sick Children, Great Ormond-street.—The treasurer of Charing Cross Hospital has received a donation of £1000 from Mrs. Jane Gabriel for the endowment of a bed in the new wing of the hospital in memory of her husband.—Under the will of Mr. J. Lewisohn of the firm of Messrs. Lewisohn Brothers and Co., £750 are left in trust for distribution among such London hospitals as the executors may choose.—Mrs. H. A. Dodds of Cheltenham has under her will bequeathed £100 to the Bristol Royal Infirmary, £100 to the Bristol General Hospital, and £50 to the Bristol Blind Asylum.

SCHOOL BOARD FOR LONDON.—The annual report of the school management committee has just been published. It is packed with interesting details concerning elementary training of the young in the metropolis and we recommend its perusal to our many readers who now make a study of educational questions.

CENTENARIANS.—Mrs. Carew-Wilson of Clifton, Bristol, has just celebrated her hundredth birthday.—*The Times* of Jan. 7th announces that Mr. Charles Green, who died at Brighton on Jan. 6th, was born at Selsey, near Chichester, on August 22nd, 1794, and was therefore in his 110th year. He was the son of a farm labourer and worked on farms in the neighbourhood of Chichester until he was 90 years of age. When no longer able to work he went to live with Mr. and Mrs. Hall, his son-in-law and youngest daughter, at Brighton. In this narrative of longevity nothing is said as to the verification of the date of Mr. Green's birth, and it is now found to be possible that he was 11 years younger than he believed himself to be.

THE PLUMBERS REGISTRATION BILL: MEETING AT THE MEMORIAL HALL, FARRINGDON STREET.—On Dec. 29th last a meeting of registered plumbers in London was held at the Memorial Hall for the purpose of the annual election of members to serve on the London Registration Committee, Mr. Charles Hudson, Past-master of the Worshipful Company of Plumbers, being in the chair. It was stated that there are now upon the register some 12,000 or 13 000 masters and operatives and it was announced that a petition to Parliament was in course of preparation in favour of the national registration of plumbers, on lines approved by the Local Government Board, as a means of distinguishing competent workmen. The desirability of some such Bill has frequently been urged in THE LANCET, for though much good has already been done by the Plumbers' Company, the promoters of the movement, it has been unable to do more than touch upon the fringe of the question, the necessary stimulus being wanting to induce the bulk of the men to join a movement which entails responsibility and expense for but little apparent advantage to themselves. If the Bill became law the case would of course be entirely altered and a proper control would be placed in the hands of the executive over the members, the numbers of whom would be vastly increased.

Appointments.

Succ[illegible] Public Institutions, [illegible] this column, are [illegible]ected to the Sub- [illegible] morning of each [illegible]

BONNEY, W. VICTOR, M.S., M D. Lond , F.R.C.S., M.R.C.P., has been appointed Tutor in Practical Midwifery in the Middlesex Hospital Medical School

BUSH, PAUL JAMES, M R C S , L.S.A., C.M.G., has been appointed Medical Officer to the Bristol Post Office. (Corrected notice.)

BROWN THOMAS, M.D , Ch B. Vict., has been appointed Resident [illegible] to the Public Dispensary, Leeds.

[illegible] appointed [illegible]

[illegible] L.S A., D P.H Lond., has [illegible] H.M. Prison, Dartmoor.

JONES A WEBB, F.R.C S , has been appointed Honorary Surgeon to [illegible]

MA[illegible] L.S A., [illegible]

MU[illegible]ifying [illegible] of the [illegible] county of Fife.

PORTEOUS, HERBERT LLEWELLYN, L.R.C.P. Lond , M R C S., has been re-appointed Medical Officer and Public Vaccinator for the S[illegible] District of the Cirencester Union.

[illegible] S., has been appointed Certifying [illegible] for the Works of Messrs. Boyd and [illegible]y of Somerset.

[illegible] Medical [illegible]

VAUGHAN, E[illegible] Physician [illegible] Free Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARMY MEDICAL SERVICE.—Examination of Candidates for not less than 30 Commissions in the Royal Army Medical Corps.

BETHNAL GREEN INFIRMARY.—Assistant Medical Officer. Salary at *rate of £100 per annum, with board, lodging, and washing.*

BIRMINGHAM GENERAL HOSPITAL.—Casualty Assistant Physician. Salary £50 per annum.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S W.—Clinical Assistants for three months.

CHELTENHAM GENERAL HOSPITAL. — House Surgeon, unmarried. Salary £80 per annum, with board and apartments.

CROYDON GENERAL HOSPITAL.—Honorary Member of the Junior Staff.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence.

HULL ROYAL INFIRMARY.—Fourth House Surgeon. Salary £50, with board and apartments

LINCOLN COUNTY HOSPITAL.—Senior Male House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

LEEDS GENERAL INFIRMARY.—Ophthalmic and Aural House Surgeon. Board, lodging, and washing.

LEICESTER INFIRMARY.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing.

LIVERPOOL STANLEY HOSPITAL.—Second House Surgeon. Salary £80 per annum, with board, residence, and washing.

METROPOLITAN HOSPITAL, Kingsland road, N.E.—Surgeon.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.—Registrar. Honorarium of 50 guineas.

NEW HOSPITAL FOR WOMEN.—Surgical Assistant, Clinical Assistants, Two Senior Assistants, and Assistant Anæsthetist.

ROCHDALE INFIRMARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, residence, and washing.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Clinical Assistants.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

ST. MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—Honorary Surgeon. Also Honorary Assistant Surgeon.

STOKE ON TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Assistant House Surgeon for six months. Honorarium of £25, with board, apartments, and washing.

TIVERTON, DEVONSHIRE, INFIRMARY AND DISPENSARY.—House Surgeon and Dispenser. Salary £80, with board, residence, &c.

UNIVERSITY OF LONDON.—Examiners—Two in Medicine, Two in Surgery, Two in Pathology, One in Materia Medica and Pharmaceutical Chemistry, and One in Mental Diseases.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon, for six months Honorarium of £25, with board and lodging.

WEST HAM AND EAST LONDON HOSPITAL, Stratford, E.—Resident Medical Officer for six months. Salary at rate of £120 per annum, with board, residence, &c.

WESTMINSTER GENERAL DISPENSARY.—Honorary Surgeon.

WOLVERHAMPTON EYE INFIRMARY.—House Surgeon. Terms £70 per annum, with rooms, board, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeon under the Factory Act at Rothbury, in the county of Northumberland, and at Dublin, in the county of Dublin.

Births, Marriages, and Deaths.

BIRTHS.

CADDY.—On Dec. 11th, 1903, at [illegible], the wife of Arnold Caddy, F.R.C.S., of [illegible]

CHIENE.—On Jan. 2nd, at Alv[illegible] of George L. Chiene, F.R.C.S. Edin., of a son.

KENNEDY.—On Wednesday, Jan. 6th, 1904, the wife of Angus Kennedy, L.R.C.P., M.R.C.S., L.S.A., of a son, at Plaistow, E.

DEATHS.

CREE.—On Dec. 29th, 1903, at Pinewood Sanatorium, Wokingham, Edward Russell Cree, Lieutenant Colonel R.A.M.C., aged 45 years.

HUE.—On Dec. 24th, 1903, at Dresden, John William Hue, M.A., F.R.C.P. in his 84th year.

HUNTER.—On Dec 28th, 1903, at Lavender-hill, S.W., Frederick John Hunter, M.R.C.S., L.R.C.P.

PEIRCE.—On Dec. 31st, 1903, at S. [illegible] M.D., aged 59 years late Port Health [illegible]

THORNTON.—On Jan 3rd, at Hi[illegible] John Knowsley Thornton, M.B., C.M., J.P., in his 59th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE DIRTY RAILWAY CARRIAGE.

A GREAT many people have travelled in trains during the past fortnight and many must have noticed the dirty state of the seats in not a few of the carriages, especially where they are upholstered. On some companies' lines the carriage seats are fairly clean, while on other lines by tapping the seat only softly and with the palm of the hand clouds of dust arise. Why do not our railway companies adopt the methods of cleaning by compressed air which are so much in vogue in the United States of America or the excellent method of cleaning by vacuum? It would surely pay the railway companies and would preserve their rolling stock and might attract fresh passenger custom to the superior classes, as no one, especially no lady, cares to contemplate sitting upon a plush-covered dust bin and paying extra fare for the accommodation. They appear to do some things better in the United States. An independent expert who was commissioned to go out from this country not many months ago inspected several large railways there and among other things reported that he was particularly struck with the cleanliness and the excellent way in which all American cars were maintained. He did not see a dirty or untidy car, and one could go into a lavatory in any car and be sure of finding a row of clean towels and plenty of soap. Heavy carpets and hangings as well as plush seat coverings were almost universal and, notwithstanding the dirt-collecting qualities of these fabrics, they were all kept as clean as a new pin by means of compressed air brushes. The expert also seems to have been able to travel 400 miles during the day without arriving in clothes that were full of cinders. Here his experience must differ from that of many travellers in the United States. On many lines it is impossible to keep the dust out, but the car attendants in such cases are most obliging in helping passengers to brush themselves thoroughly before leaving the train.

MEDICAL MEN AND THE INCOME-TAX.

To the Editors of THE LANCET.

SIRS,—Recently I had the honour of being invited to travel a dozen miles to the county town and have a little conversation with the Income-tax Commissioners on the state of my finances. I had been informed that if I sent a detailed account this might not be necessary and having had a business training in my youth I was able to do this to a sixpence. I gave the cost of working under the following heads: expenses; rent, assistance, drugs, stabling, and sundries.

Nevertheless, the invitation came. It was the Christmas week and as the roads were bad I had to set off very early. On arrival I was shown into a room with other victims, where we spoke in awed sepulchral tones, and I had leisure to recall the funking-room at the college in the days of my youth. After an hour or so I was called into the examination room and nothing could exceed the courtesy of my reception. The examiners were polished gentlemen, but the explanation of their wish to see me was too ludicrous. As you see, I had used the word "stabling" as an adjective, qualifying expenses and implying straw, hay, corn, harness, repairs of carriages, blacking, &c. Someone had read it as a substantive, meaning *a building*, and I had been called to explain my extravagance over stable hire. It had not occurred to the clerks that if my horses were lodged so palatially they would also require something to eat and that there would be a column for food.

In a few minutes everything was satisfactorily arranged and I was at liberty to return to my practice and make the best excuses I could to my patients. As this all occurred in the middle of an extensive outbreak of influenzal bronchitis it was a serious matter to me. Can you urge upon the *dii majores* who rule these events that if the country medical men are to be harried in this way it might be in the summer when work is little and roads are good instead of in the midst of their poor little harvest? I am informed by a friend in the service that there is to be a special whip-up for medical men and publicans.

I am, Sirs, yours faithfully,

Jan. 5th, 1904. A COUNTRY SURGEON.

THE MOTOR-CAR IN MEDICAL PRACTICE.

IN the *Car* of Dec. 30th, 1903, which is described as a journal of travel by land, sea, and air, Dr. F. P. Wightwick sets forth the advantages of a motor-car as compared with the brougham, the victoria, or other horse-drawn vehicle. Every busy medical man knows the difficulty of so arranging his list of visits that the same ground is not traversed more frequently than is necessary, a difficulty that is increased when urgent cases, which must be seen early, are situated in widely separated directions. To those who use a motor-car this is a factor of little consequence for, as Dr. Wightwick points out, the motor-car is never tired and there are no horses to consider. Again, each journey is made in much less time and two or three hours a day are saved, giving an opportunity for a reasonable amount of recreation without diminishing the average quantity of work. Another advantage is that the motor-car can be used either as an open or closed carriage and the same vehicle is therefore to all kinds of weather. With regard to cost, the initial expense is undoubtedly heavy, but not more so perhaps than the buying of two [illegible] necessary stable appliances. [illegible]uble-cylinder petrol car built [illegible]d. It has a brougham body with extended roof and glass front, similar to the French limousine car, and is fitted with pneumatic tyres. The windows of the brougham let down in front, at the sides, and at the back, so that the amount of air can be regulated to admit almost as much as there is in front of the car, or to make it the same as a completely closed carriage. The annual cost, the writer thinks, is difficult to compare accurately with that of a carriage, since the amount of work done with a motor-car is so much greater. On an average his carriage expenses formerly came to rather more than £400 a year. The expense of his first year with a motor-car, which is based upon an actual experience of nine months, the remaining three months being calculated on the same ratio, amounts to just over £300; but this is rather a high estimate, he says, as the expenses of the remaining three months are not likely to be so great since the first nine months include the summer months and holidays, when, of course, the mileage is greater and the wear and tear are more severe. Further, the second and subsequent years will probably be less expensive as a considerable amount of experience has to be bought by the novice. The article concludes as follows. "It comes then to this, that while doing three or four times more mileage with infinitely greater comfort and marked improvement to health I spend £100 a year less, and this saving could be increased considerably by taking smaller stables in a less expensive neighbourhood (the distance from home being of little moment to a motor) and, of course, by using solid instead of pneumatic tyres, although this could hardly be advised. Another item, which is almost a necessity in London, is the heavy premium for insurance against fire, accident, and employer's liability. This sum, of course, is included in the estimate of annual expenditure above given." It should be mentioned that the writer says that he has travelled over 10,000 miles without a serious breakdown.

THE SELF-CONSUMING CIGARETTE.

To the Editors of THE LANCET.

SIRS,—I have been smoking Wills's gold flake cigarettes for some ears (those sold in packets, not tins) and I notice that when a lighted igarette is put down it burns itself away after the manner of an gyptian cigarette. This used not to be so. Evidently something as been lately added—quite lately. I am anxious to know if this new ded matter is prejudicial to health.

I am, Sirs, yours faithfully,

Jan. 1st, 1904. T. W. W.

* We have examined the cigarettes in question and no new ingredient has been added. The observation of T. W. W., however, is quite an accurate one. The explanation depends probably upon variations in the amount of fusible salts. Tobacco that has been damped may lose a certain amount of its fusible salts and consequently tends to self-consumption. The cigarette made of such tobacco is not abnormally prejudicial to health.—ED. L.

"DUMP."

To the Editors of THE LANCET.

SIRS,—No one can fail to notice the increased use of the word [illegible] THE LANCET. I have [illegible] ssed in a "Dictionary [illegible] published in Boston [illegible] 1877 (fourth edition) and by Messrs. Trübner and Co. in London, [illegible] which is evidently a standard work, that "the word is used [illegible] Devonshire in the sense of to knock heavily, to stamp; hence [illegible] bably its American application." So probably the victorious [illegible] ater is, after all, a prodigal son who has returned to the [illegible] erland unrecognised on account of being wrapped in the Stars [illegible] Stripes. It is inevitable that this sort of thing should [illegible] pen where two nations have a common stock and a common [illegible] guage. The famous air of "Yankee Doodle" is said by many to be [illegible] old English air called "Nankey Doodle" and to have originally [illegible] n attributed to Dr Shack- [illegible] while others say that the [illegible] old Dutch harvest song. [illegible] sidering the early connexion of New York (formerly New Amster- [illegible]) with Holland neither origin is improbable. To return to the [illegible] "dump," the shortest intelligible explanation of the word which [illegible] ve yet seen is "thump," with which word it seems etymologically [illegible] nected.

I am, Sirs, yours faithfully,

[illegible] ndon, Dec. 19th, 1903. "H. DUMPTY."

A MANUFACTURER OF MECHANICAL LIMBS.

[illegible] James Gillingham, surgical mechanist, of Prospect House, Chard, [illegible] s forwarded to us some photographs similar to those recently [illegible] epted from him by Her Majesty the Queen showing a few of the [illegible] ients to whom he has supplied artificial limbs. Mr Gillingham's [illegible] ry is interesting to readers of THE LANCET. From his account, [illegible] ich accompanies a portrait of one William [illegible] s wheelbarrow, we le[illegible] the late Viscount I[illegible] t while ramming home a charge at the cannon's mouth, at [illegible] celebration of the wedding of the King, on March 10th, 1863. An arm was devised by Mr. Gillingham, a bootmaker, of Chard, and presented to the keeper by the inventor. When the late Sir William Fergusson saw the arm he remarked, "The ingenuity that devised and made this arm can make a leg." These words turned Mr. Gillingham from a boot manufacturer to a surgical mechanist. His original invention was favourably noticed in THE LANCET of Oct. 13th, 1866. We find, on referring to our files, that we gave full particulars of this accident to the gamekeeper with two figures of him with and without the apparatus, showing that he could make practical use of the artificial arm which several makers in London had said they could not contrive. We are glad to think that surgical instrument makers are more ingenious now than they were then, for the firm of Gillingham and Son is only one of many in the kingdom whose mechanical skill proves of incalculable value to the surgeon. This does not alter the fact that in 1866 Mr. Gillingham seems to have "wiped the eye" of the best of them. Sir William Fergusson's words appear to have fallen upon fruitful ground.

RED OR BLACK INK FOR PLACARDS?

A CORRESPONDENT writes as follows:—

> "For some time past I have noticed the curious tendency of placards printed in red ink to fade within a short time under the influence of exposure to light considerably quicker than those printed in black ink. I have noticed, for example, that the placards of the National Association for the Prevention of Consumption which are posted in the carriages of various railway companies become after a comparatively short time scarcely readable, even at a distance of 12 inches from the observer, and the difficulty of discovering what the placard says is a good deal more at night under artificial illuminants. I am of opinion that good black ink is far preferable for such placards, being more durable, economical, effectual, and less trying to the eyes. I am quite sure that many persons must have noticed the curious effects presented sometimes by words, especially names, which have been printed or painted with the first letter of each word in red ink and the rest in black. After a time, at a distance of a few yards, such names as Box, Clark, and Blake become apparently Ox, Lark, and Lake. I have observed many comical effects of this sort. I can only say, beware of red ink, especially of red capital letters."

POOR-LAWS ON THE CONTINENT AND IN AMERICA.

To the Editors of THE LANCET.

SIRS,—Can you, or any of your readers, refer me to published books, pamphlets, or reports in which I can obtain information as to the working of Poor-law medical relief and sanitary administration in continental countries and America?

I am, Sirs, yours faithfully,

Jan. 5th, 1904. L. KIDD.

"THE WONDERS OF MODERN SURGERY."

UNDER this title Dr. C. W. Saleeby contributes to the January number of the *World's Work* a picturesque account of some surgical methods and appliances, but he must not expect members of his own profession to regard his article as a scientific contribution. Commencing with a sketch of the use of ether and chloroform in the production of general anæsthesia, he traces the development of antiseptic surgery, gives illustrations of its practical value, and forecasts its hereafter in the following peroration:—

> If there be radium in the sun, and if the human race may therefore expect a future of, say, 50,000,000 years, then for so long will antiseptic surgery be saving lives and limbs and eyes, averting pain and sorrow and reducing weeks or months of illness to days or hours. From King Edward VII. to the nameless aboriginal treated in a missionary hospital, and from 1870 to the year 3,000,000 or so, runs the host of those whom antiseptic surgery claims for the exercise of its beneficence.

The illustration of lectures with lantern pictures thrown on a screen and Dr. Doyen's representation of surgical operations by the agency of the kinematograph next come under review, followed by references to recent improvements in Cæsarean section and to the modern operation of suturing wounds of the heart. The facilities gained for brain surgery by raising portions of the skull with the flaps of the scalp and the safety with which other incisions in bone or compound fractures (as in osteotomy for knock knee) may be intentionally produced provide material for a column. Brain surgery leads on to excision of the Gasserian ganglion and laminectomy, after which the scene changes to gastrostomy and the feats accomplished by "ladies' doctors." The Roentgen rays naturally receive attention in a popular exposition such as this and the text is illustrated by skiagrams as well as by a picture of a patient under examination for renal calculus.

Dr. Saleeby has treated his theme in a satisfactory way, having regard to the fact that he is writing for the laity and bound by the *terms of his title* to give prominence to the apparently miraculous. But his memory has misled him in some points of detail—such, for instance, as the statement that antiseptic surgery was "born in Edinburgh during the memorable years (1869-77) ... .." Medical writers of articles for the general reader may also be indebted to him for some hints in happy phrasing. "Crisis of the maternal function" as a synonym for childbirth deserves commendation.

SUBSTITUTION UNMASKED BY THE ROMAN LETTER "M."

A CORRESPONDENT writes:—"With reference to your annotation 'Substitution Unmasked by the Roman Letter "M"' stamped on the bottom of a loaf of bread according to the Bread Acts of 1822 and 1836, I should like to warn some people who may be looking now for 'M' on the bottom of their loaves not to mistake the 'VV' which is the mark stamped on the bottom of their loaves by the 'Vis Vitæ' Bread Company for an 'M' which could easily be done. This bread is largely sold by small grocers and general shops to their customers and there are a great many of the purchasers who do not know what 'Vis Vitæ' may mean in full and when abbreviated to 'VV' they invariably take it to be an 'M.'"

THE VAGINAL DOUCHE.

To the Editors of THE LANCET.

SIRS,—Referring to this subject and to the letter of Messrs. Down Bros. I consider that the glass vaginal pipes should be made with one large hole at the end as it gives a better stream as a douche and should be used, if possible, through a speculum.

I am, Sirs, yours faithfully,
Welbeck-street, W., Jan. 2nd, 1904. HEYWOOD SMITH.

PATENT HYGIENIC UNDERWEAR.

WE have received specimens of underwear from a firm entitled the Doctor's Supply Company of Stockport, which appear to us to have much to commend them. They are soft and warm and elastic. The company are acting as agents for the Rasurel underwear, clothing made of wool and peat fibre blended, and inclose samples of these goods. We have already noticed the Rasurel underwear favourably in our columns, having had a report upon them showing that they are soft, comfortable, and do not shrink. The samples now offered for inspection, like the previous ones, are well made and finished. The address of the Doctor's Supply Company is 82, Wellington-road South, Stockport.

A SOAP TIDY.

THERE is no doubt that a considerable amount of soap is wasted in the soap dish as is obvious from the fact that much of the soap will be found in it, or below it in the case of a perforated tray being used, in a state of jelly. The "soap tidy" is designed to obviate this waste and to keep the lavatory basin and its accessories clean. It dispenses with a soap dish altogether. In the "soap tidy" the cake of soap is fastened to a strap wound on a wheel controlled by a spring. The wheel and the spring are inclosed in a neat copper box. The cake of soap may be placed in a netted bag or a cord with a ring attached may be imbedded in the soap. When the soap is required for use the cake is simply pulled downwards into the basin and after it has been sufficiently used it will return when released by the action of the spring to its original suspended position. In this way the soap readily dries instead of keeping wet and wasting. The principle is exactly that of a spring tape measure with a cake of soap tied to the end of it, the measure being fastened to the wall. The patentees are Messrs. Dean and Farrar, Well-lane, Halifax.

THE REMOVAL OF HOUSE REFUSE.

A CORRESPONDENCE is taking place in the *Times* on the evils of the present system of removing house refuse, a matter with which we have on several occasions dealt in these columns. Under the heading of "How not to do it" Sir Henry Thompson has called attention to the insanitary methods of dust collecting adopted by the local authorities in London and judging from the interest taken in the matter by other correspondents it would seem that public attention may at last be aroused to the fact that the present system of removing house refuse is a pernicious one. We hope that the London County Council and the municipal authorities of the City and the boroughs will lend a ready ear to suggestions for reform. The present Lord Mayor of London, when sitting on the bench at Guildhall recently, is reported to have referred to the opinion of Dr. W. Collingridge, the medical officer of health of the City, that loafers turning over the contents of dustbins constituted a danger to the public health, as "sanitary madness." Dr. Collingridge was, of course, perfectly right in insisting upon the risks to public health that follow upon the disgusting practice and we trust that Sir James Ritchie has now altered his opinion. Sir Henry Thompson points out that the transference of house refuse to the dust carts by means of coarse wicker baskets is a completely wrong method and suggests that the dust cart should give place to a vehicle containing light metal receptacles with covers, which receptacles should be filled from the house and taken directly to the carts. Another correspondent suggests that dust vans should be "light skeleton vehicles holding a number of covered galvanised iron bins and as the collection is made from house to house an empty bin should be left to take the place of the one removed." Such a system would have obvious advantages and the trifling additional expense entailed would be compensated for by the increased health and comfort of everyone concerned.

"DOODLE DASHERS."

THIS appears from a report of a recent meeting of the Torquay town council in this week's *Torquay Directory* to be the name given to certain paper brushes used on the Torquay pier on the occasion of fêtes. The brushes are poked into each other's faces by gay sojourners at Torquay, while even members of the Baths and P Committee are alleged so to disport themselves. In spite of su grave support, and of the statement made by a town councillor th "hundreds of visitors would be disappointed if they could not 'doodle dashers' in their innocent recreation," a recommendation the sanitary committee of the town council to prohibit the sale "doodle dashers" upon the pier was carried. It was shown that form of "innocent recreation" was dangerous and insanitary.

◆

Owen writes:—"I shall feel much obliged if any of your readers be kind enough to give me authentic information on the followi points: 1. Where can I refer to recorded cases of a permanent separate odontoid process of the axis or second cervical vertebra man? 2. Does the comparative term 'neurapophysis' apply on to the lamina of a vertebra, or does it include the correspondi pedicle as well?"

Recently Qualified.—The best course is to consult a practitioner of cognised standing in the neighbourhood. The circumstances detailed point to the advisability of not accepting the invitation contest the appointment.

Mr. G. P. James.—The address of the Medical Defence Union is Trafalgar-square, W.C.: secretary, Dr. A. G. Bateman. The addre of the London and Counties Medical Protection Society is 3 Craven-street, Strand; honorary secretaries, Dr. H. Woods an Mr. A. G. R. Foulerton.

M.O.H. will find the exact situation discussed in our pamphl "Difficulties under the Infectious Diseases (Notification) Act."

E. F. B. C. is recommended to pay no attention whatever to a pe fectly natural condition of things.

ERRATUM.—In our analytical notices last week, under the heading of "India Pale Ale," the name of the firm should have been given *Warwicks* and Richardsons. The former name was mis-spel "Warricks."

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

IT is most important that communications relating to the ditorial business of THE LANCET should be addressed xclusively "TO THE EDITORS," and not in any case to any entleman who may be supposed to be connected with the ditorial staff. It is urgently necessary that attention be iven to this notice.

t is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II of 1903, which was completed with the issue of Dec. 26th, were given in THE LANCET of Jan. 2nd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1903 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s*., by post 2*s* 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

METEOROLOGICAL READINGS.

An Address

ON

SOME FORMS OF CHRONIC ABDOMINAL SURGICAL DISEASE.

Delivered before the Bury and District Medical Society on Nov. 24th, 1903,

BY E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON, ANCOATS HOSPITAL, MANCHESTER.

MR. PRESIDENT AND GENTLEMEN,—In the first place, permit me to offer you, the members of this society, my sincere thanks for the honour you have done me by requesting me to appear before you to night and to deliver to you an address on a subject connected with my own special work, that of abdominal surgery. Your very courteous secretary made only one stipulation and that was that it should be one of general interest. I have endeavoured to comply with that proviso by asking your attention to certain points connected with some of the more chronic forms of abdominal disease.

Acute abdominal diseases with their lightning-like onset, their rapid course, and their often tragic endings appeal to that dramatic sense that is more or less present in us all. They arrest the attention and compel their study and the rapid growth of the surgery of this region has thrown great and almost complete light upon their causation, pathology, and treatment. Chronic diseases have none of this attractiveness. The commencement of any one of them is so gradual that it is often extremely difficult to fix its date within a period of weeks or months; its course is for a long time frequently associated with but indefinite symptoms and when at length it terminates fatally the final result is brought about by so many complicating pathological states that even a post-mortem examination may fail to apportion correctly the amount of damage done by the orignal factor. Perhaps for this very reason they deserve, and will repay, closer examination. Many of these conditions, moreover, are capable of efficient treatment and even cure by surgical means if they can be detected before such complications arise. Such cases are found especially in connexion with the digestive tract, either in this alone or in connexion with those two main accessory secretory glands, the liver and pancreas, and the tubes which convey their secretion into that tract.

Many researches, such as those of Bloch, Terrier, Gilbert, Girode, Lippmann, and others on the bacteriology of the biliary passages, go far towards legitimising the belief now very generally held that the formation of biliary calculi is greatly favoured, if it is not entirely caused, by the presence in the gall-bladder and ducts of micro-organisms which [illegible] bert and Lippmann[1] [illegible] not absolutely sterile, [illegible] but the organisms [illegible] naerobic, being the micrococcus ovalis of Escherich, the bacillus perfringens of Veillon and Zuber, and the bacillus radiiformis of Rist and Guillemot, none of which are pyogenic. Once only they found the staphylococcus albus and in two cases the colon bacillus. The same observers, however, found that the fluid obtained from the bile passages at the time of operations for biliary calculi was always fertile—that is to say, that when grown upon culture material it always showed colonies—and they say that whenever aerobic micro-organisms were present they invariably belonged to the species of the colon bacillus, the most frequent of all being the colon bacillus itself; this is, to use their own expression, "le grand envahisseur des voies biliaires." Gilbert, Fournier, and Domenici[4] found the bacterium coli in a certain percentage of gall-stones, whilst Chiari and Dufourt cite cases in which gall-stone formation apparently took place as a consequence of previous attacks of typhoid fever. Ochsner[5] also emphasises this connexion between typhoid fever and biliary calculi. He has noticed also a connexion with previous attacks of appendicitis. Other writers have suggested the effect of previous attacks of influenza, typhus fever, and some other infective diseases in assisting this formation.

Scott Carmichael's experiments on animals, on the other hand, appeared to him to justify the opinion that concretions can be formed in the gall-bladder without the presence of the bacterium coli or typhosi He introduced pebbles, glass beads, or balls of pith into the gall-bladders of dogs and found concretions of carbonate of lime deposited upon them, never of cholesterin, and this was not altered when, as in some cases, he injected cultures of typhoid fever or other organisms either at the same time or at a later date. It might be suggested in connexion with this statement that a more exhaustive examination should be made of all stones removed from the gall-bladder or ducts. The specimens I show evidently differ greatly not only in form but in composition, and it might be found that just as in the urinary tract we have three or four well-defined species of calculi which differ in appearance, seat of origin, and symptoms, so also here all biliary calculi may not be formed in the same way or in the same locality, as they certainly are not of the same material, and that this difference may have some connexion with the site of their formation. Thus, cholesterin stones are certainly more often found in the gall-bladder and might prove to be always formed there; bilirubin calcium stones are often found in the ducts and may prove to be usually formed in the liver, passing down the hepatic duct whilst of small size and gradually enlarging in consequence of deposits from the bile which would be constantly in contact with them, and so on. This might explain why in some cases we find single stones whilst the more frequent variety is multiple and faceted, why in some cases they are found only in the gall-bladder, in others in the common duct, and in still others, of which this is a good specimen, in which minute gall-stones were found in almost every duct in the liver besides the large one seen, which was impacted in the immensely dilated common duct.

Naunyn[6] perhaps sums up the question in terms which all may accept "The invasion of bacterium coli constitutes at any rate an occurrence to which stagnation of the bile can occasionally lead, and which is capable of producing cholangitis and cholecystitis, and these again may give rise to the formation of gall-stones."

When once cholecystitis has commenced it may end in suppurative cholecystitis, empyema of the gall-bladder, or gangrene of the same organ; the inflammation may spread along the pancreatic duct and produce acute hæmorrhagic pancreatitis or pancreatic sloughing and abscess, but these conditions are outside the purpose of this address; they are only mentioned in order to emphasise the untoward possibilities which may follow the entrance of infective material into the biliary passages. The main importance of them to us at present is the suggestion they carry that possibly a closer observation of patients who have at any time suffered from typhoid fever or any of the other infective diseases previously mentioned might bring to light earlier symptoms than those upon which we are accustomed to rely. Such early symptoms would be of very great value and would probably be such as would escape the patient's own notice or, indeed, that of any but the trained observation of the patient's own medical attendant.

If the symptoms produced by the presence of biliary calculi are reviewed they will be found to be very obvious in some cases but somewhat vague and confused in others. Repeated attacks of colicky pain more or less referred to the right hypochondrium with transient jaundice and absence of bile from the stools coincidently with its presence in the urine, are all old and well-known signs. But the last three are by no means always present. The difference between the older and later views on this subject is well shown by [illegible] of Surgery published [illegible] of a cystic tumour [illegible] means of diagnosis, especially with a [illegible] presence of calculi. No one, I presume, would suggest this now. Every operating surgeon knows that when calculi are present it is quite the exception to find any enlargement of the gall-bladder, much less one that could be felt. On the contrary, this viscus is usually shrunken and contracted and may be difficult to find, tucked away as it is under the right lobe of the liver, even when the abdomen is opened. Courvoisier[7] has formulated the law that in 80 per cent. of such cases there is contraction of the gall-bladder, whilst in 90 per cent. of cases of enlargement of the gall-bladder the obstruction is due to other causes. Of far more value is the painful point described by Robson,[8] which is found one inch above and to the right of the umbilicus, or to be exact at the junction of the upper two-thirds with the lower third of a line drawn from the ninth rib to the umbilicus and which, like the McBurney point in appendicitis, is painful on deep pressure. Another test, described by Murphy of Chicago,[9] is extremely useful. The patient is placed in the sitting position, bending forwards; the examiner, standing behind, insinuates his fingers beneath the edge of the ribs on the right side, the finger tips being bent upwards; when the abdominal muscles are sufficiently relaxed to permit the lower edge of the liver being recognised the finger tips are pressed as far as possible beneath its lower surface. The patient is made to take a deep inspiration. The diaphragm forces the liver down until the gall-bladder touches the examining fingers when the inspiration suddenly ceases as though it had been shut off. Whilst definite indications are of course of most value it is of equal importance that not too much weight should be attached to the absence of symptoms which the force of previous teaching may have led us to expect but which the later light obtained by operation has shown to be untrustworthy. Thus jaundice, even temporary, is only present when calculi block the hepatic or common duct. Its absence is no proof that the gall-bladder itself is not packed with calculi. The absence of bile from the stools or its presence in the urine has simply the same significance. The absence of the time honoured pain in the right shoulder I have so frequently noted that I have ceased to attach any serious importance to its presence or absence. In several of my cases the pain has been felt below, between, and over the scapulæ, especially the right, but it has seldom been felt higher. Its occurrence appears to mark only certain positions of the stone after that has entered the common duct.

[6] Loc. cit.

Passing now from diagnosis to the question of treatment at the outset a most important consideration arises. Since the formation of calculi presupposes—if we accept the evidence I have given above and other evidence which is available but which there is no time to detail—some amount of inflammatory sepsis in the biliary canals, which may lead to more acute and destructive changes, is it wise to delay the removal of these foreign bodies and the drainage of these canals until symptoms become imperative? In the parallel case of urinary calculi no such delay would be advised and the possible or probable advent of a chronic cystitis would be considered an additional reason for anticipating this by prompt removal of the foreign body. In all the cases which I have operated upon some amount of inflammatory change either in the walls of the gall-bladder and ducts or as evinced by the presence of pus in the contained fluid has been present, whilst in all but one the symptoms of auto-intoxication or inflammation have promptly disappeared within a few weeks of the cholecystotomy. Of course, in saying this, I am excluding those cases which were associated with carcinoma

Prolonged presence of biliary calculi has other and no less objectionable results. I have already referred to pancreatitis. This has been shown by Opie, Halstead, Lancereaux,[10] and Moynihan[11] to depend, sometimes at least, upon the presence of a stone in the ampulla of Vater, which damming back the current of bile from the common duct favours its entrance into the duct of Wirsung and so produces infection of that canal, gradually spreading further and further into the pancreatic tissues. Should that infection produce destruction of the islands of Langerhans glycosuria will result and the prospects of a successful operation be reduced almost to a minimum Short of this, impaction or lodgment of a calculus in the common duct will cause jaundice and its accompanying impairment of coagulability of the blood, greatly increasing the risk of prolonged capillary hæmorrhage during and after interference My first case, that of a woman, aged 52 years, in whom symptoms had only existed for 12 months, died from this cause. At the necropsy 11 days later no other cause of death could be found but a large quantity of clots in the peritoneal cavity. This case occurred in 1897 before the advantages of a preliminary dosing with calcium chloride were so well appreciated as they are now, owing to the advice and example of Mayo Robson. Even now, however, there is a great advantage in being able to anticipate if possible the occurrence of this complication.

Other consequences of the retention of calculi in the biliary ducts, whilst perhaps not so clearly demonstrable, equally merit attention. Papillomata of the gall-bladder, adenomata of the bladder and ducts, and especially cancer, have all been observed in connexion with these formations. How far the latter may be looked upon as a consequence of the continuous and prolonged irritation they produce is even yet a very debateable point. Robson says that as a primary affection of the ducts cancer is rare and that it is usually secondary to gall-stones or to extension from adjoining organs. Zenker[12] found gall-stones in 85 per cent. of all cancers of the gall-bladder and Musser fixes the percentage at 69 per cent., Courvoisier at 85·7 per cent., and Brodowski at 100 per cent. Naunyn believed that half of the cases of chronic jaundice diagnosed as cholelithiasis are complicated with cancer or are due to cancer alone.

That cancer does not always follow even very prolonged existence of biliary calculi is evident from numerous cases detailed by various operators. A case of my own may be of interest in this relation. In April, 1903, Mr. J. D. Willis of Manchester brought for operation a woman, unmarried, aged 48 years, with the following history. She had suffered from attacks of colicky pain in the epigastric and right hypogastric regions at intervals since she was 16 years old—i.e., for 32 years. When four years old she was taken to New Zealand, where she lived for 18 months. After her first severe attack which did not last long, she was free from pain for from four to five years, when she had a severe illness lasting about eight months. During this time she was jaundiced but had never been so since. In the course of this illness a suppurating hydatid cyst appeared and burst externally in the epigastrium. Since this time she had never been free for any length of time from attacks of pain. Five or six years ago the pain was very severe and more continuous for about 18 months. Some of these attacks had been associated with vomiting, but not all, and she attributed its occurrence to the morphia she had been given hypodermically. Her last attack was on April 10th and 11th, 1903. These attacks had been recurring every week or fortnight, but for the last few weeks they had come on as often as two or three times a week. They had nothing to do in point of time with the menstrual periods which had been regular until the menopause two years ago. The patient was of good colour, with no jaundice, but she had lately lost flesh. Each attack was described as beginning with a dull ache over the liver or a feeling of indigestion; the acuter pain sometimes started suddenly and sometimes remained subacute for a long time, gradually increasing. At times she felt a dull pushing sensation in the right hypochondrium; at times it made her jump by a shooting sensation. Aching also was felt across the back below the shoulder blades. It was worse on the right side, sometimes over the scapula, but it never went up to the acromion. There had never to her knowledge been bile in the urine or a want of it in the fæces. On April 19th cholecystotomy was performed and a single unfaceted stone was removed from the gall-bladder. Nothing was felt in the ducts. There was a long Riedel's lobe hanging down like the flap of a saddle for five or six inches below the general line of the liver. When this was drawn up the omentum was found firmly adherent beneath to it, to the pylorus, the stomach, the colon, and the duodenum. After these adhesions were separated the small contracted gall-bladder was found deep down in its fissure. Drainage was used as some muco-pus escaped on removal of the calculus. Ultimately the wound entirely closed and in October Mr. Willis reported that she was in perfect health.

Nevertheless, the frequent association of carcinoma with cases of long-standing cholelithiasis must have great weight in the prognosis and should, I conceive, add additional force to the indication for earlier removal of calculi when once their presence is demonstrated than has previously been the case.

Although the tumour I show you is not connected with the presence of gall-stones its extremely rare character may render it interesting in any discussion bearing upon hepatic growths. I have not been able to find in the literature any description of a similar one nor, as I understand, has Mr. Mayo Robson, in the third edition of whose work, about to appear, it will be figured. It has already been described and figured in The Lancet.[13] It is, as you will see, the gall-bladder itself, transformed into a multilocular cystic mass, and was removed in December, 1900, from a woman, aged 42 years, sent to me by Mr. J. E. Harburn of Buxton, who had complained for 18 months of a sensation of weight with heavy, dull sickly pain. She had had two attacks of jaundice, the last eight years previously. There was a rounded solid body in the gall-bladder area moving with respiration and moveable to some extent from side to side. After removal, which was somewhat difficult owing to the presence of very large veins in the strongly adherent omentum, the intestine also being adherent, she recovered and went home perfectly well two months later.

Passing from this region I ask your attention to another large class of chronic abdominal complaints, those, namely, affecting the large intestine. Before anything is said as to the diseases which affect this viscus it is interesting to note Dr. R. W. Leftwich's views[14] as to the mechanism by which its function is carried on. Formerly its contents were believed to be equally under the influence of peristalsis, as are those of the small intestine—that is, that they were gradually forced onwards by a wave of muscular action in its own walls. It is evident, however, that if this is the case the process is carried on under conditions differing from those [illegible] estine is free [illegible] its two main [illegible] fibres of the [illegible] in the large intestine they are almost wanting except as three strong bands placed at an equi distance around. These fibres are not continuous with those of the small intestine, which end at the ileo-cæcal valve, but start afresh from the appendix, to which they are the best guide. The circular fibres of the small intestine form a well-marked and important coat which is pretty equally thick in its whole extent; the circular fibres of the large intestine are comparatively much more scanty and not so equably distributed. The canal of the small intestine is but slightly different in calibre in all its parts and any difference is gradually produced; the canal of the large differs widely [illegible] here [illegible] al is [illegible] the [illegible], are separated by a distinct valve which seems to emphasise their different functions. These functions are themselves very distinct, for whilst the small intestine performs a great part in the digestion and absorption of food and can only very secondarily be regarded as a sanitary apparatus the large intestine completely reverses this, and whilst absorption from it is but small, must be looked upon chiefly, if not entirely as the drainage system *par excellence* of the body. The small intestine with the stomach is the kitchen which pours its refuse into the slopstone and drain of the cæcum and colon.

Dr Leftwich points out the remarkable similarity of the large intestine taken as a whole to a syphon. "A syphon," he says, "consists of a reservoir, a sh[illegible] a long descending one. [illegible] reservoir is the cæcum, [illegible] long is the ascending co[illegible] consists of the descendi[illegible] and the rectum about [illegible] length being, therefore, about double that of the short tube and likely to act as a very efficient syphon. The sigmoid flexure has been left out of the account as its curves probably neutralise each other." But it is curious to notice that this acts like the S shaped trap in modern drains. In fact, the wh[illegible] e model upon which [illegible] sanitary appliances. [illegible] he brings forward in an extremely well reasoned paper which will well repay perusal Dr. Leftwich concludes that the contents of the large intestine are carried forward mainly by syphonage, although peristaltic action is also present to a subsidiary extent, and he justly adds that the light thus thrown upon a great natural process cannot fail to suggest many ideas for improved treatment; for example, in the treatment of fæcal accumulation by enemata the hips should be raised to prevent syphonage and too rapid regurgitation. The patient should remain quiescent for 20 minutes and then resume the erect position somewhat suddenly; in the treatment of diarrhœa the same elevation of the hips will tend to retard the too frequent emptying of the bowel, and so on.

Most morbid conditions affecting the large intestine are mainly chronic in character and extend in their whole course over long intervals of time, although many of them signalise [illegible] earlier symptoms to which I have already referred are so much to be desired. It is evident that here is a large gap in our knowledge which succeeding observers will probably be able to fill with immense benefit to those under their care and to the profession. In the majority of instances at present attention is first directed to them either by difficulties in evacuation, constipation, or by too frequent action —diarrhœa. To these fundamental symptoms may be added some peculiarity in the stools themselves—the passage with them or at other times of blood, mucus, or pus, the existence of pain, or the presence of some abdominal swelling. Later, especially in those cases characterised by constipation, distension of the abdomen may be produced and this may be local or general. This symptom is, however, always a late one and in any case which may require surgical interference it should, if possible, be anticipated as its presence greatly and needlessly increases the risk and signalises changes in the intestinal wall which militate strongly against a successful result. It is, of course, scarcely necessary to point out how immensely it hampers any thorough examination, especially bimanual examination.

Given a condition of difficult and painful defecation the attention should first be directed to the anus and rectum. Hæmorrhoids may be discovered and, if these are large, and especially if they are inflamed and tender, one is apt to be satisfied with their presence as a sufficient explanation. That this is not safe, even if the patient is comparatively young, is of course perfectly well understood but is very clearly emphasised by the following case. In June, 1901, I was asked to see a woman, aged 31 years, by a Manchester surgeon. For three or four years she had complained of pain in the anal region. 12 months earlier she suffered from influenza and for the first time noticed some loss of blood which had gone on ever since. She had always been constipated but this had become worse during the last 18 months. When this gentleman examined her he found several piles and removed them but the symptoms continued and increased. On complete recto-bimanual examination a circular nodular hard mass was found in the upper rectum which had caused a certain amount of invagination. Colotomy was performed and later the growth was excised by Weir's method. It proved to be, as expected, a cylindroma of the rectal wall. The patient died three days after the last operation.

Some obscure cases of pain in the rectum require very careful examination before the cause can be discovered. In October of this year my friend Mr. Harburn of Buxton sent to me a young married woman who complained of an intense burning pain after defecation some distance up the rectum. There was no fissure, no sentinel pile, and digital examination at first discovered nothing abnormal. The history given was that during her only confinement the bowels were moved with some pain and that ever since this suffering had been more or less present. At last a point was felt just at the upper edge of the internal sphincter on the right side which was extremely tender to touch. The description given by Bryant of ulcer of Morgagni's valve supplied the explanation. Evidently some portion of hard fæces had been forced past the child's head during the confinement which would be made to scrape the posterior wall of the gut. This, catching one of Morgagni's valves, had torn it slightly, sufficiently to expose a nerve end. Free dilatation of the sphincter showed the presence of a small ulcer which was cauterised by the electric cautery, with the results that all pain ceased and did not return.

A complete rectal exploration is therefore necessary in all cases before we can arrive at an accurate diagnosis. And opinions greatly differ as to what a complete rectal diagnosis means. Most surgeons, however, of the present day would hardly consider it complete until the possibilities of touch and sight have been exhausted. It is astonishing how much may be learnt by touch alone if both hands are employed. Recto bimanual examination will enable the examiner to make out very accurately the position and contents of all the organs in the pelvis, not only in the woman but in the male, and I have more than once diagnosed a carcinoma of the sigmoid flexure by this means which was so easily depressed into the pelvis from above that simple palpation of the abdomen utterly failed to detect it. Other conditions outside the bowel, such as enlarged prostate, impacted ureteral calculus, and most of the female pelvic disorders, which are so many that it is impossible even to touch them now, may be detected in this way, the latter often much more clearly than by the vagino bimanual method.

[14] Edinburgh Medical Journal, 1902, New Series, vol. xii., p. 536.

The work of Martin, Gant,[15] and of Hirschman[16] has demonstrated the importance of the rectal—Houston's—valves in producing when enlarged and thickened a train of symptoms which form a variety of constipation only to be cured definitely by their division or partial removal. Hirschman details these symptoms as follows: "Inability to defecate properly or comfortably. The patient is constantly straining at stool and passes nothing but small, hard, apparently broken-off pieces or a long ribbon-shaped stool, accompanied or not with mucus. The condition has lasted a long time. Cathartics have lost their effect Defecation does not give him relief; the rectum may feel hot and is constantly overloaded and stuffed. Defecation is infrequent, the patient going from two days to a week without a stool." In such a case digital examination may not recognise the condition, although these valves will usually be felt to be more rigid than usual. The greatest amount of information will be gained by the use of a fair-sized proctoscope, of course after an enema has cleared the parts, when the valves will be easily seen and their enlarged and rigid condition recognised. Should such rigid valves be present purgation and enemata are alike useless for the purpose of overcoming the habitual constipation produced by them. The only remedy is their division or removal to some extent. In these cases Gant has advised the use of small clamps which are applied through the proctoscope by a special holder. These clamps produce necrosis of the parts within their grip and drop off when this has been followed by separation of the sphacelated parts. Hirschman cuts off a portion of the thickened valve and unites the divided mucous membrane edges by sutures. I confess that I do not like to leave foreign bodies, either clamps or sutures, in a septic cavity such as the rectum if it can be avoided; it is impossible to be certain how far the necrosis produced by a clamp will extend. It is equally impossible to be certain that the sutures introduced may not act as setons, being impregnated with the rectal discharges. In these cases I have divided the valve by the electric cautery knife. This has the advantage that it leaves no foreign body behind; that the cauterised edges are protected by an aseptic slough, which permits no access of decomposing material until a granulating surface is produced in which are no open lymphatic orifices; and that cauterisation produces a sequent contraction in the remaining tissue which assists in widening the lumen, since the contraction is in a direction away from this It has in my hands been followed by the best possible results. And in this connexion much might be said of the advantage in all such cases of thorough dilatation of the sphincter. Almost all cases of proctitis and, indeed, of any intra-rectal irritation are associated with spasmodic contraction of this little muscle. This in its turn by preventing perfect evacuation tends to perpetuate the trouble and it is often astonishing how much may be done towards relief and cure of many troublesome cases in which there may be but slight organic mischief to be detected by the thorough dilatation of the anal sphincter This, however, must be dilatation, gentle and gradual, not divulsion

Passing higher up the bowel it is only possible to advert very briefly to growths in the sigmoid flexure. This is a very favourite site for cylindroma, the form of carcinoma most often met with in the large intestine Not all obstructive growths, however, are malignant, at least in their early stages. Here, for instance, is a pure adenoma which produced an intussusception of the sigmoid flexure and was removed by Maunsell's operation. In March, 1900, Mr J Wilde Smith of Manchester requested me to see with him a man, aged 43 years, who had noticed pain over the hypogastrium seven years previously after lifting some heavy pieces of cotton. Since that time he had passed blood and mucus from time to time with tenesmus. Both these symptoms were increasing and latterly had been so frequent that they were occurring ten or 12 times in the 24 hours. On examination an intussusception of the upper part of the rectum could be felt high up, its lower extremity being covered by a soft growth which bled slightly and broke down easily under the finger. Colotomy was first performed and a fortnight later, after thorough disinfection of the lower segment, the abdomen was opened in the middle line; the mass was easily found and removed by Maunsell's operation, the abdomen being closed without drainage. Three months later the permeability and sound healing of the lower segment being evident, the colotomy wound was closed. Mr. Smith writes on Nov. 20th, 1903 (more than three years after): "Although this man is leading a very reckless life, he is in very good health and has never had any symptoms of recurring obstruction."

A great difference of opinion exists as to whether it is advisable to perform a preliminary colotomy in such cases. To my mind there appears to be an immense advantage in having the area of operation and the line of union produced by suture of the large intestine free from fæces until such union is firm—after which the fæcal current can with safety be turned into its normal channel again by closure of the colotomy opening. In this case that was what was done and this illustration shows the result. There is only one difficulty. The two skin wounds are not far from one another and from one, the artificial anus, is more or less constantly issuing infective material. How is this to be prevented from contaminating the other wound? The fæcal fluid, if there is any diarrhœa, will soak into dressings and thus render them septic, often very soon after they have been applied. I have found that this can be thoroughly prevented by building a semi-circular rubber dam with gutta percha tissue moistened with chloroform in such a way as to interpose a damp-proof barrier between the two. The chloroform moistened gutta-percha adheres firmly to the skin and no fæces can pass it. It is also an advantage to seal the second wound, that through which the growth has been removed, by celloidin, which also offers an impermeable barrier to infection from without.

Appearance of abdominal wall ten months after operation.

The treatment of muco colitis, in its many forms with and without ulceration, which may be specific, gonorrhœal, simple, lupoid, herpetic, dysenteric, or cancerous, has been greatly assisted by the clearer ideas which have been gained of the actual condition of the interior of the gut since the more thorough use of the proctoscope and sigmoidoscope; the newer silver salts, especially protargol and argyrol, have supplied us with agents which are not rendered ineffective by the rapid formation of an inert albuminate as was the case with the older nitrate, but permit of far deeper and further reaching action upon the tissues and the micro organisms which have penetrated them. So large a field of new observations and new methods of treatment is present here that it would have been easy to take up all the time this evening by going over it alone. This was impossible but I must mention one. At last some use has been found for the appendix, that abortive organ which has been so much denounced as an entirely superfluous viscus. In certain cases of mucous or membranous colitis which relapse after all treatment apparently because local applications fail to reach the cæcum, the cæcum itself has been opened, an artificial anus has been made, and the large gut has been washed out from end to end. Weir[17] has proposed that instead of making a new opening into the cæcum the appendix should be found, brought through the abdominal wall, and fixed there. Its end being cut off, its lumen is utilised as the channel for injections. Of course care must be taken that this little tube is not ulcerated and that it is permeable. When once the tissues have returned to their normal state this can either be removed in the usual way or, which seems preferable, its minute opening can be closed, itself remaining ready for use again should the condition relapse. Weir, and following him Meyer,[18] have reported cases in which this method has answered admirably and it certainly appears to be a valuable addition to our operative resources in combating these at present often most unsatisfactory cases. In the one case in which I have used it the proceeding was perfectly easy to carry out and was most successful.

---

[15] Boston Medical and Surgical Journal, April, 1903, p. 473.

[16] Medical Record, May, 1903, p. 767.

As was evident from the first, a large number of chronic abdominal surgical conditions have been necessarily excluded from consideration. To mention no others, there is a large field for description and discussion in growths peculiar to women, but sufficient has been said, perhaps, to emphasise the proposition with which I started—viz., the necessity for constant observation of chronic cases with a view to the discovery if possible of new symptoms which will throw light upon their earlier stages and which may act as danger-signals, so that effective surgical interference may be carried out whilst there is every reason to expect a successful issue and before dangerous complications have arisen, or at least before they have reached such a stage as to render all our efforts ineffectual.

It only remains for me to thank you for the patience with which you have listened to what, I am well aware, has been but a feeble and ineffectual attempt to place this question before you.

PHYSIOLOGICAL OR FUNCTIONAL ALBUMINURIA.[1]

BY SAMUEL WEST, M.D. OXON.,
PHYSICIAN AND LECTURER ON PRINCIPLES AND PRACTICE OF MEDICINE, ST. BARTHOLOMEW'S HOSPITAL; CONSULTING PHYSICIAN, ROYAL FREE HOSPITAL, ETC.

THE problem of physiological albuminuria from its clinical side presents itself thus. A patient has albumin in the urine without any sign of organic disease, what is its significance and importance? The difficulty here lies, as it does so often in medicine, in applying general rules to the individual case The cases of albuminuria fall into two groups according as the cause lies in the kidney itself or not. Where the kidney is not itself the organ at fault the cause may be found in the heart or in abnormal conditions of the circulation, in blood changes or other general conditions, and in each case alike the cause may be obvious or not obvious. In a third group of cases the urine is normal when secreted, the albumin being added to it as it passes from the kidney to the exterior. The following table makes the classification plain:—

Cis- or pre renal { Cause obvious—e g. [illegible]
Renal... ... ... [illegible]
Ultra- or post-renal—accidental, from urinary or genital passages, &c.

Physiological albuminuria might, therefore, be described, as this table suggests, as albuminuria in which the cause is not obvious. This makes plain the indefinite character of this group of cases and the difficulties which attend the diagnosis.

The first thing to be done clinically in a case in which albumin is found in the urine is to exclude all accidental contamination—i.e., to make sure that the albumin is not added to the urine after secretion on its way from the kidney. In women such contamination is common from the vagina and uterus but it can easily be eliminated by obtaining a clear catheter specimen. There remain, however, in man and woman alike other accidental sources which are not so easy to exclude—e g., discharges from the urethra, the prostate, the bladder, the ureters, and the pelvis of the kidney. The presence, for instance, of a small calculus in the pelvis of the kidney may lead by its irritation to the occurrence of albumin, as it does of blood, without other symptoms of its presence. This is especially true of an oxalic acid calculus and even of oxalic acid crystals too. An extreme instance of this kind is the copious albuminuria attending an acute attack of gout, when for the first day or two the urine may be loaded with albumin which disappears as rapidly as it came when the attack subsides. Some of these accidental causes are by no means easy to eliminate. Supposing this to have been correctly done the next step is to exclude all cases where there are obvious lesions in the kidney or morbid conditions elsewhere in the body sufficient to explain the albuminuria—e g., morbus cordis, fevers, certain conditions of the blood, &c. This is generally not a difficult matter.

There then remains a group in which no cause can be found to which the albuminuria can be referred. The patient, therefore, is assumed to be healthy and the albuminuria is called physiological or functional. What physiological or functional albuminuria then means is that every care has been taken to find a cause but without success. It does not, however, follow that because a cause has not been found no cause exists and that the albuminuria is but an accident of health. Physiological albuminuria, therefore, is a diagnosis based partly on fact and partly on opinion. The fact is certain. The opinion may be open to question and its value depends upon the care which has been bestowed upon the investigation of the case. It is a pity, therefore, to use a term which seems to beg the very question which has to be proved. The term "functional" seems to me even more objectionable than "physiological" as being still more indefinite and vague.

Other terms have been suggested such as intermittent, cyclical, postural, and dietetic, but they are all open to objection. I think it would be best to discard the term physiological or functional altogether and to speak of the condition as *albuminuria in the apparently healthy*. This shows where the difficulty lies, for it is often impossible to be certain that the patient is in fact healthy.

Whether it be called physiological or functional the first inquiry which the name suggests is this: Does albuminuria occur under normal or physiological conditions? It is stated that albumin may be demonstrated in the urine of everyone in some such way as the following. Urine, in which the ordinary tests have failed to show albumin, is concentrated and the residue is dissolved and carefully tested. Then a trace, very minute it may be but still sufficient, may be demonstrated by delicate tests The explanation of this seems obvious. There is a constant shedding of epithelium throughout the urinary passages. If this epithelium be concentrated, collected, and dissolved it will, of course, give the reaction for albumin. After all this question is of academic interest rather than of clinical importance, for no one suggests that albuminuria is ever physiological in the sense that albumin may be demonstrable by the ordinary means in the unconcentrated urine of any and every one.

Statistics showing the frequency of albuminuria in the apparently healthy differ widely. Thus examinations made in the ordinary routine of out-patient practice yield a percentage of 1, 2, or 3 as the case may be. More careful examinations made *ad hoc* raise the percentage several points, it may be to 10. Again, frequent examinations at different times of the day may show albuminuria present at one time and not at another. In this way by careful examinations frequently made and with varied delicate tests the percentage may be considerably raised.

For the purpose of the Lettsomian lectures in 1899 I had a long series of observations made by the late Dr. Levison which yielded one of the highest percentages obtained—viz, 42. The analyses of these results are very instructive. First, it may be noted that of healthy persons nearly 60 per cent. show not the slightest trace of albumin with any test at all. Of the 40 per cent., in nearly one-half the form of albumin was not serum albumin but nucleo-albumin, and that *only in very minute trace*. Of the 20 per cent. in which the albumin was serum albumin, in about one half the trace was so minute that it would have been overlooked in ordinary examination. Thus we arrive at 10 per cent. in which the albumin would have been discovered by the ordinary methods of testing—a percentage which is not far removed from that of ordinary experience. Finally, even in this residue of 10 per cent. the amount was in most cases extremely small. The frequency of albuminuria varies considerably at different ages. Of healthy infants 10 per cent., it is said, present albuminuria and among the somewhat older patients of a children's hospital it has been shown in about 20 per cent. The most abundant statistics are for the period of school life among boys—and after that for young adults—when the percentage may reach as high as 20 or so. Albuminuria stands at its lowest level about the age of 25 years and from that period continues to rise regularly and rapidly with the age.

---

[17] Medical Record, August 9th, [illegible]
[18] [illegible]
[1] A paper intr[illegible] Society of London on Dec. 14th, [illegible]

Functional albuminuria is very often intermittent and varying in amount. It has sometimes been called cyclical but the regularity of its recurrence depends upon the regular recurrence of the cause—such as changes of posture from the recumbent to the erect position, as on getting up in the morning, exercise, diet, digestion, bathing, exposure to cold, &c. In most healthy persons, however, none of these conditions is competent to excite albuminuria. There must therefore be some other cause or peculiarity which determines it and careful clinical investigation will in many cases succeed in finding one. It is, of course, dangerous to make a diagnosis of disease upon a single physical sign. But the converse is also true and it is equally dangerous to assume that because no other abnormal sign can be discovered the one physical sign present can be disregarded and the individual pronounced healthy.

I now turn to some of the more special difficulties which arise in practice.

1. *The fact that albuminuria is intermittent, occasional, or cyclical is no proof that the kidneys are sound.* In a case which is convalescent from acute Bright's disease and presents no albuminuria while confined to bed, the albuminuria may return on getting up or be brought back by very slight causes, such as changes in diet, exposure to cold, &c. In fact, all the peculiarities of functional albuminuria may be reproduced. Here it must be agreed that the kidneys, though getting well, are not yet sound. Indeed, as convalescence proceeds the causes referred to fail to produce albuminuria and the recovery is regarded as complete. Of course, in most of these cases the albuminuria is associated with the presence of casts and cells, but, as stated, a few cells may be found in the urine of everyone and the real significance of a few hyaline casts is not yet agreed upon. Then, again, in granular kidney the albuminuria may be intermittent and may be absent for long periods of time and the urine contain few, if any, casts or cells.

2. Again, though in functional albuminuria the amount of albumin is tiny or but a small trace, this may be so in granular kidney; while in convalescence from acute nephritis, where convalescence is not complete, a small amount of albuminuria may persist without other symptoms for years. Even in functional albuminuria the amount is not always small. There are cases described, though they are rare, in which the amount was as much as one half or more.

3. Again, the clinical importance to be attached to the albuminuria varies greatly with the age of the individual. In newly born babies and infants albuminuria without obvious cause is by no means uncommon. The same holds good to some extent of older children. It is common experience that little children are easily upset by improper or impure food which, besides causing intestinal disturbance, rashes such as urticaria or erythema, and even fever, may lead to transient albuminuria. In fact, in young children all the functions are in a condition of instability. The organs and tissues are not seasoned and resistant; their condition is easily disturbed by slight causes which in older children and in the adult would produce little, if any, effect. On the other hand, the processes of growth and development are active and recovery is rapid and complete in children where in the adult it would be prolonged and often incomplete. Hence the experience in children cannot be applied without considerable qualification to more advanced periods of life.

4. It is between the ages of 15 and 25 years—that is to say, in boys at school and young adolescents—that functional albuminuria has been most frequently described. The statistics at these age periods are abundant and they prove that albuminuria is very common in apparently healthy young people. This is the time of rapid sexual development and naturally the albuminuria has been referred to this cause. The two facts are coincident but there is no reason whatever to believe that they are related. The same is true of masturbation; in this case, at any rate, what evidence is forthcoming is strongly opposed to such an explanation.

The boys at school who present what is called functional albuminuria fall into two groups: the one florid, full-blooded, vigorous lads with good or high pulse tension, the other pale, flabby, not well conditioned, and with low arterial tension. The two groups probably present differences in the pathology and prognosis and demand different treatment and management. The significance of these cases can only be determined by watching their subsequent history. Some, the majority, get quite well soon. In some the albuminuria persists for a time but ultimately disappears, in others it is persistent, while in the residue signs of organic kidney *mischief ultimately reveal themselves.*

Speaking generally functional albuminuria in boys raises serious questions, for though many seem perfectly well and others get quite well still the fact that others do not get well and the difficulty of deciding to which category any individual case belongs introduce factors of uncertainty in forecasting its future. The practical question which is certain to be raised in these cases is this: "Shall the school life of the boy be interfered with?"—a question of very great gravity to the boy and his parents and of great anxiety and responsibility to the medical attendant. Unless there are special reasons in the particular case—and each case of the kind has to be settled not upon general principles but upon its own merits—careful consideration and the balancing of all the *pros* and *cons* generally end in leaving the boy at school under the careful and constant supervision of his medical attendant. The risk has to be run by the boy and fortunately in most cases the risk proves to be slight and the result is satisfactory.

5. In the young adult, up to the age of 25 years or thereabouts, the questions are the same but of still greater importance, as the answer given may involve the loss of an appointment or of the power to effect a life insurance, upon which much may depend. At this age period—i.e., between 20 and 25 years—the frequency of albuminuria stands at its lowest. After the age of 25 or 30 years the frequency of albuminuria rises as age advances and its significance becomes more serious. Its gravity is also more easy to demonstrate, for statistics bearing directly on the question are available from insurance offices. In my Lettsomian lectures I referred to some experience on this point and I may be excused if I reproduce some of the figures I then quoted to prove the increased risk there is in these cases and the necessity of protecting the life offices against them. From the data stated a calculation was made for me by an actuary to show approximately the difference in mortality compared with healthy males.

Ages attained.	Rate of following year.		Ages attained.	Rate of following year.	
	Rate from figures given.	Rate for healthy males.		Rate from figures given.	Rate for healthy males.
30	—	—	50½	3·70	1·97
32	1·53	1·06	52½	2·64	2·20
34	3·27	1·11	54½	3·74	2·13
36	3·33	1·16	56½	7·13	2·69

The numbers are, of course, too small to lay any stress upon the actual percentages, but the figures show in a general way how largely the presence of albuminuria raises the mortality as well in those below 40 years of age as in those above. This introduces the question which runs through all the age periods alike but becomes most pressing after the age of 30 years—viz., the existence of latent kidney disease, in other words, the relation of these cases to granular kidney. That this relation must be fairly close, closer than is generally thought, is demonstrated by the diagram which shows the curve of granular kidney and that of albuminuria to be of the same character.

In granular kidney it is known that the albumin in the urine may vary greatly in amount; that it is often a mere trace; that it may be absent altogether, even for long periods; that it may not be associated with casts or renal cells; and that in its occasional and varying character it may present all the features attributed to functional albuminuria. Further, granular kidney is a very insidious disease which may lie latent or be undiscovered for years. It is a disease of long duration and, though the period of greatest mortality is in middle life, it must, running the chronic course it does, have existed for many years previously. In other words, the beginning of granular kidney has to be looked for in quite early life. Thus many cases of advanced or fatal granular kidney occur under the age of 30 years, some are met with under 20 years, and a few even in children. Granular kidney has been even described in infants, but as it is not in accord with our general pathological experiences to believe that advanced fibroid degeneration of any organ can develop in a few weeks these cases in infants probably have a different pathogeny and may be attributed to some intra-uterine or congenital defect of development. Interesting as these cases undoubtedly are they do not affect the general point at present under consideration—viz., the fact that the commencement of the pathological process which leads ultimately to granular kidney must be referred to early life, even to the period of adolescence or puberty, the very age at which functional albuminuria is most frequently described.

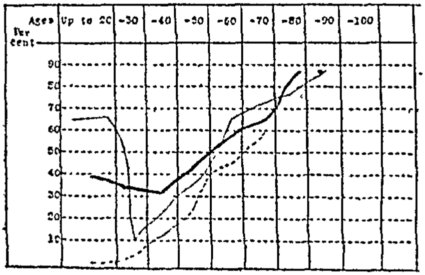

Diagram constructed from collated statistics given by Stirling (light line) and Levison (thick line). The dotted line shows the frequency of granular kidneys in proportion to healthy kidneys. It is drawn in accordance with Mahomed's figures.

If then there is no age at which granular kidney may not be present or be developing, it is evident that some of the cases of so-called physiological or functional albuminuria may be early cases of granular kidney in which the other signs of that disease are not yet developed, or in which that disease has been either not sought for or even overlooked. It is therefore important that in all cases of functional albuminuria careful search should be made for the signs of granular kidney. Of these signs, besides albuminuria, the most important is *arterial thickening (arterial sclerosis)*. Of arterial thickening there are two well-known forms—atheroma in advanced life and that associated with granular kidney in middle and early life. Besides these two there is no other widespread or general arterial sclerosis recognised. Arterial thickening is not uncommon in young people and it can hardly be due to atheroma. There is, however, in my opinion, one other form of arterial thickening which is met with in the young and lusty. This is probably a physiological hypertrophy. It is seen in athletes and is, I believe, due to a hypertrophy of the muscular coat of the larger arteries similar to that which occurs in the heart. I have seen not a few cases in which this seemed to be the only admissible interpretation. With this exception, however, so far as I know, arterial thickening in the young must always be looked upon with suspicion. Thickened arteries may suggest granular kidney when albumin is absent and albuminuria may be due to granular kidney when the arteries are not especially thick, but the association of the two conditions is very serious.

Thickened arteries are not sufficiently and systematically looked for in the young. If they were they would be more frequently found. In many of the statistics of physiological albuminuria no reference whatever is made to the condition of the arteries and this omission certainly goes some way to vitiate the importance of the figures given. If these con- [illegible] it conclude [illegible], the so- [illegible] appreciably increased risk to the life and that this risk increases rapidly with age. The rules which have been laid down are sound and fully justified—viz., to reject all such lives above the age of 40 years, to load them heavily between 30 and 40 years, to make some addition to every case under 30 years, and to wait awhile and to watch the cases in adolescence and youth. To which general rules may be added the still more important one to reject at once at every age those cases in which the albuminuria is associated with arterial thickening.

The conclusion of the whole matter may be summed up thus:—

1. Albuminuria may occur as a transitory symptom in persons who, except for this symptom, may be judged to be perfectly healthy, for they appear to be so at the time and remain so.
2. But it may also occur in persons who though they appear at the time to be healthy develop signs of disease subsequently.
3. It is difficult to distinguish at a given time between those who will remain well and those who will not.
4. It is difficult to exclude for certain many of the pathological causes to which the albumin might be due. In other words, though there may be no proof that these causes are present there is equally no proof that they are absent and in some cases the result shows that they were not absent.
5. Speaking generally, the larger the amount of albumin in the urine and the longer it persists the greater the probability of some permanent disease.
6. Continued observation of these cases shows that the so-called physiological albuminuria does very appreciably increase the risk of life and that this risk grows rapidly with every year of age after 30 years.

As the result of the foregoing proposition we are led to the general conclusion that functional albuminuria is never, strictly speaking, physiological at all, but that it is, on the contrary, always pathological though not necessarily renal.

Wimpole-street, W.

THE TERMINATION OF A CASE OF RECURRENT MAMMARY CANCER TREATED BY OÖPHORECTOMY.

BY G. ERNEST HERMAN, M.B., F.R.C.P. LOND.,
F.R.C.S. ENG.,
CONSULTING OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

IN THE LANCET of June 11th, 1898, p. 1612, I published a report of a case of recurrent mammary cancer treated by oöphorectomy. The cancer was noticed and removed in October, 1890. At the end of 1896 it had recurred and had invaded the axilla and neck so extensively that removal of the recurrent growths was impossible. In March, 1897, the ovaries were removed. By September of that year none of the recurrent growth could be felt. The patient remained in good health until the autumn of 1901. During the greater part of September, October, and November she had evening pyrexia and perspirations, the cause of which was not found out although repeated careful examinations were made. In January, 1902, she again had evening pyrexia. In February she had an attack of pain in the region of the left kidney so severe as to need the injection of morphia. In March she began to suffer from epigastric pain after taking food. In October Dr. G. C. Tayler of Trowbridge, her medical attendant, discovered an oval, elastic, painless swelling in the line of the sagittal suture, near its anterior end, measuring about one inch by three-quarters of an inch. This increased slowly in size during the rest of her life. The epigastric pain continued and in January, 1903, she began to have dorsal pain. In March attacks of vomiting commenced and her feet became œdematous. There was then no albumin in the urine. Later fluid was felt in the abdomen. In May a little blood was twice present in the urine. Her breathing became so difficult that she could not lie down.

On June 1st she had retention of urine and Dr. Tayler was unable to pass a catheter because of her inability to lie down. The patient died on June 3rd. No necropsy was made but I think there can be little doubt that she died from recurrent cancerous growths in internal organs.

The result of oöphorectomy in this case was that it gave the patient four and a half years of good health. The cases in which up to 1900 oöphorectomy has been performed for inoperable recurrent mammary cancer have been brought together by Mr. Stanley Boyd. The broad result which they show is that in about one-third of the cases the patient obtained "more or less marked benefit," this benefit consisting of retrogression of the cancer and a period of a few months or years of good health. This is too much to be accounted for by chance.

A distinguished surgeon has said that he has "not the courage nor the faith" to propose this operation for inoperable mammary cancer. What he is afraid of I cannot imagine. The objections that I can understand being urged against oöphorectomy are three. First, the immediate risk to life. This in competent hands is very small; but even were it larger than it is the life of a patient with incurable cancer is not very valuable to herself. Second, the temporary suffering caused by the operation. Every abdominal section is followed by two or three uncomfortable days. This is not much in comparison with the possibility of benefit Third, the effect of removal of the ovaries on certain functions. This in a patient certain to die soon from cancer is not worth considering. Against these drawbacks we can tell the patient that there is one chance in three that the disease will retrogress and that she will have some months, perhaps some years, of good health. I agree with Mr. Boyd that in cases of inoperable mammary cancer oöphorectomy ought to be offered to the patient. The drawbacks and the possibility of benefit should be put before her and she should be allowed to choose. And I think that if she asks the surgeon to help her to decide he should advise her to have it done.

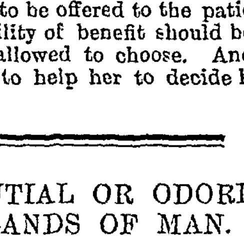
Harley-street, W.

THE PREPUTIAL OR ODORIFEROUS GLANDS OF MAN.

By ARTHUR KEITH, M.D. Aberd., F.R.C.S. Eng.,
LECTURER ON ANATOMY, LONDON HOSPITAL MEDICAL COLLEGE;
AND
ARTHUR SHILLITOE, M.B. Cantab., F.R.C.S. Eng.,
SURGEON TO OUT-PATIENTS, LONDON LOCK HOSPITAL.

In a considerable proportion of males in whom some slight degree of hypospadias is present certain curious and symmetrical markings are to be seen on each dorso-lateral aspect of the prepuce. These markings, which are represented in Fig. 1, consist of two or more crescentic reddish lines which meet above at a dorsal angle or fornix and below towards the frænum of the prepuce at a ventral fornix. They may be styled from their shape and appearance "preputial ocelli." In the oval area between the reddish lines are elevated folds on which may be seen minute openings and frequently the short stumps of hairs. An occasion arose which gave us an opportunity of examining microscopical sections through one of thes preputial ocelli. We found it studded with large wide-mouthed sebaceous glands. A reference to literature gave us no clue as to their nature; all text-book agree in stating that the skin of the distal two-thirds i destitute both of hairs and sebaceous glands. From th regularity of their form and the frequency of their occurrence in conjunction with hypospadias (they were wel marked in the last nine cases of hypospadias with hooded prepuce examined at the Lock Hospital) we had no doub that these markings were neither accidental nor pathologica but were probably remnants of some structure or organ o which we were ignorant.

Fig. 1.



Dorsal aspect of a penis in a case of hypospadias, showing the ocelli on the prepuce.

The first real clue as to the nature of these preputia ocelli was obtained from the examination of the foreskins o rodents. On the prepuce of developing rats and mice,[1] long before that structure has risen into a fold to cover the glans a circular area of epithelium grows downwards into th subcutaneous tissue of the penis and in the course o development forms a compound sebaceous gland quite a large as a sultana raisin. When the foreskin rises into a fol the duct of the preputial gland opens just inside the fre margin of the foreskin. Its secretion gives rise to a peculia odour. This gland in mice and rats is evidently formed by the submergence of an area of sebaceous glands. In the pig a preputial gland is formed in the same manner. In th rabbit there is a series of sebaceous glands round the margin of the vulval orifice, but one of them in a recess behind th fold that represents the prepuce is especially large an secretes a substance with a characteristic odour. In the cat and in most members of that tribe the sebaceous glan which secretes the sexual odoriferous substance is derived from the circumanal and not from the circumvulval series, and lies inside the margin of the anus. A more extended research showed that throughout the mammalia, and to thi law man is no exception, there is a fringe of specialised sebaceous glands surrounding the anal and urogenital apertures, which are functionally odoriferous glands and ar connected with the sexual system. With castration, b these glands round the anus or round the urogenital openings, they cease to secrete their characteristic substances.

At first our search for the preputial glands in primates, animals much more nearly allied to man than those above cited, was disappointing; an examination of human embryos at all stages of development was also, at first, without result, because we did not know where or what to look for. The first real evidence we found of them was in certain South American apes and it was not in the males, but in the prepuce of the clitoris of the females that we came across the same markings and structures as we found in the prepuces of hypospadiac man. The skin of the penis in apes and anthropoids is covered with hair and ordinary sebaceous glands. We ought to have recognised that the correlation of the ocelli with hypospadias indicated that the condition was to be sought for in the female—for hypospadias is undoubtedly a partial inheritance of a female condition.

On turning to the condition on the prepuce of the female these ocelli, sometimes poorly marked, but frequently very distinct, were always to be seen (Fig. 2). On the lateral aspect of the prepuce, in the neighbourhood of the frænum preputii, an area of large sebaceous glands was constantly found on microscopical examination, although to the naked eye they may appear to be absent. They do not occur on the dorsal aspect of the prepuce or on the skin along the dorsal aspect of the clitoris Dr. Robert Keith found them to occur on both aspects of the labia minora, an especial group being situated at each side of the clitoris in the depression between the prepuce and the labium majus. They vary greatly in development in different women. The inner aspect of the labia majora is studded with them. In a series of cases kindly inspected for us by Mr. Charles Gibbs at the Lock Hospital the following conditions were observed.

Case 1.—The patient was a quadroon, married, aged 28 years. There was a well-marked preputial fold but no evidence of glands.

Case 2.—The patient was single, aged 20 years. The prepuce and anterior extremities of the nymphæ were united into a ridge. There was no evidence of glands.

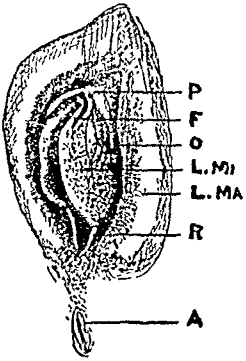
Case 3.—The patient was married, and aged 38 years. The prepuce was well marked, the clitoris being small. The upper part of the vestibule beneath the clitoris showed two small blind holes in the mid-line, which represented the lacuna magna There was no evidence of sebaceous glands.

---

[1] Mr. C. B. Lockwood very kindly placed his splendid embryological collection at my disposal.—A. K.

CASE 4.—The patient was aged 22 years, single. There was a rudimentary clitoris. The prepuce and crura were represented by a slight elevation on each side, with a depression in the centre. There was no evidence of sebaceous glands.

FIG. 2.



Vulva of a human fœtus in the seventh month. The area is faintly stippled in which sebaceous glands are found. P, Prepuce. F, Frænum. O, Ocellus. L.MI, Labium minus. L.MA, Labium majus. R, Retinaculum. A, Anus.

CASE 5.—The patient was aged 23 years, married. There was a large clitoris; the crura and prepuce were well marked; no evidence of sebaceous glands was present.

CASE 6.—The patient was aged 24 years, married. The clitoris was well marked, the crura passing down into the nymphæ. There were a slight ridge under the pink mucous membrane and a hooded well-marked prepuce. Under the lens the appearance was like a ridge of sebaceous glands.

CASE 7.—There were two distinct rows of glands, six in the external, four in the internal row in the angle between the prepuce and the labium majus; all the genitalia were more greasy-looking than usual

CASE 8.—The patient was single, aged 22 years. In the angle between the prepuce and the labium majus were four well-marked glands on the left, not so obvious on the right.

CASE 9.—The patient was married, aged 24 years. The nymphæ were covered with sebaceous glands which extended to the prepuce. On the left side was a row similar to that in Cases 7 and 8. The whole [illegible]

CASE 1[illegible]

CASE [illegible] The sebaceous glands in the angles between the labium majus and the prepuce were continuous with those of the nymphæ.

CASE 12.—The patient was a half caste negress, single, aged 29 years. She had a well marked prepuce and clitoris. There was a large number of sebaceous glands on the nymphæ, extending to the edge of the prepuce; none were present on the prepuce.

CASE 13.—The patient was a blonde. There was no pigmentation about the vulva. No sebaceous glands could be seen. In brunettes they are better marked.

CASE 14.—The clitoris, prepuce, crura, and anterior extremity of nymphæ were united *into a curved ridge*. There were one or two depressions in the vestibule like the orifices of glands.

CASE 15.—There was a pale pink mucous membrane. No sebaceous glands could be seen.

CASE 16.—The same conditions were present as in Case 15.

CASE 17.—The patient was single. Sebaceous glands were present in the angle between the labium majus and the prepuce but none on the prepuce. The genitalia were very greasy.

CASE 18.—The patient was married. There were sebaceous glands extending up to the clitoris.

CASE 19.—The patient was married. The prepuce was well marked; there were no sebaceous glands.

CASE 20.—The patient was single and aged 21 years. The sebaceous glands were well marked in the angle between the labium majus and the prepuce, also on the prepuce.

CASE 21.—The patient was single. There were well-marked sebaceous glands from the hair of the mons Veneris to the prepuce. These were huge and arranged in parallel rows. She had an atrophied uterus and her breasts were wasted. One ovary was removed five years ago.

CASE 22.—There were a large prepuce and clitoris, with smegma. No sebaceous glands were to be seen on the prepuce.

CASE 23.—The patient was single and aged 22 years. There was a well-marked bunch of sebaceous glands extending to the prepuce.

In the male department out of 504 cases examined during the months of July and September, 47 cases, or 1 in 10·7, were found to have abnormally placed meatus. 13 of these showed two or more openings through which the urine was passed. Since the end of May we have seen nine cases as depicted in Fig. 1. One of the nine showed two well-marked ridges extending from the ventral fornices, downwards, to be lost behind the misplaced meatus urinarius.

With this knowledge of the distribution of the sebaceous glands in the female to guide us we found that there was constantly present in the skin of the penis a series of glands beginning in the ventro-lateral aspect of the prepuce (see Fig. 3) and stretching backwards along the ventral aspect on each side of the raphé and ending in the ordinary sebaceous glands at the root of the penis and base of the scrotum. This gave us a clue to certain vexed points concerning the homology of the labia minora in the male. In the male these folds grow together on the ventral (perineal) aspect *of the penis; the series of sebaceous* glands on the ventral aspect represents the glands of the labia minora in the female. The retinacula of the labia minora, shown in Fig. 2, are the only parts which directly assist in forming the floor of the male urethra. Thus the conclusion we were led to concerning the nature of the preputial ocelli, found in cases of hypospadias, is that they are, like the condition of hypospadias itself, inherited from the female. In the same manner the male inherits the nipple and breasts and the rudiments of a vagina and uterus, and further, that the circumvulval or odoriferous glands of man are similar in nature to the corresponding glands of mammals, but in him they are developed in the female and only represented as rudiments in the male.

FIG. 3.

In the course of this research we failed to find any trace of Tyson's glands which have been described in every text-book of anatomy published since Tyson's time. *To quote from* the last edition of Quain's Anatomy: "Numerous sebaceous glands are collected round the cervix of the penis and corona glandis; they are named the glands of Tyson or glandulæ odoriferæ, their secretion having a peculiar odour." It shows the strength of the faith of anatomists that they have for nearly two centuries described glands which have not, and never had, an existence. Further, there is no written evidence that Tyson ever described or observed such.

On turning to a paper by Professor Tandler and Dr. Paul Döměny[2] we found that a number of leading continental investigators had denied their existence from time to time during the last 20 years; they, however, had failed to find sebaceous glands in the prepuce as well as in the corona of the glans or the neck of the penis. They describe, however, a number of cysts in the neighbourhood of the frænum preputii.

Whence, then, comes the smegma which is found beneath the prepuce? It certainly is not secreted by glands. Before discussing its origin it is necessary to turn to the development and nature of the prepuce. Rather more than two years ago Dr. D. Berry Hart published in the *Journal of Anatomy and Physiology* an excellent paper dealing with the morphology of the human urino-genital tract. In that paper he set forth quite a new view of the development of the prepuce. Up to the time he published his paper everyone regarded the epithelium which joins the prepuce to the glans penis as having been buried there by the growth of the prepuce forwards over the glans. He, on the other hand, regarded the epithelium as a solid ingrowth, which starting from the neighbourhood of the meatus urinarius, shelled off, as it were, a layer of skin to form the prepuce. One of us accepted that view and gave it prominence in a text-book on embryology. But on investigating the matter we found that the old account is the correct one—namely, that the prepuce is formed as a fold that rises up and grows forward like a hood over the glans. As the prepuce grows forward three changes occur: (1) a new epithelium is formed on its deep surface, the lining cells arising from the epithelium covering the neck of the penis; (2) deep ingrowths of epithelium take place during the last month of fœtal life into the free margin of the prepuce which is thus thrown into folds (if this process is arrested phimosis is the result); and (3) that in the lateral aspects of the penis ridges of epithelium grow into the prepuce and give rise to folds. In cases of hypospadias in the male, and as a normal process in the female, these ingrowths are few in number and limited in extent. It is these ingrowths which give rise to the red lines seen in the preputial ocelli. The epithelium which covers the neck of the penis and lines the prepuce is of a peculiar nature. It is clearly allied in structure and nature to the epithelium which forms the sebaceous glands. When the cells desquamate they are transformed not as are the cells of the skin into a corneous substance but into a substance closely allied to sebum—smegma.

The skin of the penis of man is peculiar in being destitute of hairs. In that man differs from every other primate. This we believe is due to the fact that the skin on the dorsum of the human penis is, comparatively speaking, an insertion or new growth that separates the prepuce from the skin over the symphysis pubis. The origin of the dorsal skin of the penis characterised by the absence of hairs and sebaceous glands may be related to the posture in which connexion is effected in man.

CARCINOMA OF THE DUODENUM; RESECTION; RECOVERY.

By G. A. SYME, M.S. Melb., F.R.C.S. Eng.,
SURGEON TO THE MELBOURNE HOSPITAL AND ST VINCENT'S HOSPITAL; LECTURER ON ANATOMY, UNIVERSITY OF MELBOURNE.

Carcinoma of the duodenum is rare; according to Ewald out of 1148 cases of carcinoma of the intestine only 19 were in the duodenum. "If a malignant tumour is found obstructing the duodenum, resection is practically impossible."[3] The following case in which a constricting carcinoma of the duodenum was successfully removed is therefore of interest.

A man consulted me on April 3rd, 1903, complaining of "indigestion." He stated that his age was 40 years and his occupation that of a farmer; he was married and had four healthy living children; his wife was healthy and had had no miscarriages. He was perfectly well up to two years previously when he was suddenly attacked with a violent pain which he located to a point a little to the right of the mid-line of the abdomen just above the navel. He also vomited several times. The attack lasted for some hours and gradually passed off. Ever since he had felt a sense of discomfort after taking food. About 12 months previously he had had another attack of vomiting after drinking whisky, and on several other occasions the same thing happened, so he gave up whisky. Some six months previously he found that he vomited some hours after eating, his food being rejected partially digested no matter what its nature. He also felt pain and discomfort after food which were relieved when he vomited. These attacks of vomiting gradually increased in frequency until they occurred daily. He had no actual pain, had a craving for food, and had tried all kinds of food with the same result. The vomit had never contained blood or bile. His weight 12 months previously was 10 stones 8 pounds; now it was 9 stones 9 pounds. He was distinctly emaciated; no tumour could be felt in the abdomen and the stomach was dilated, with distinct splashing. The heart and lungs were normal. The urine was acid, of specific gravity 1018, and contained neither albumin nor sugar. The knee jerks and other reflexes were normal. The diagnosis made was pyloric obstruction probably due to malignant growth and operation was advised. The patient was most indignant at what he regarded as a "cold-blooded proposal" and declined to have anything done in spite of careful explanations.

On August 3rd he sent for me to see him. I found him in bed, extremely emaciated, and so weak that he could hardly stand. He had been trying all kinds of quacks and latterly had been under the care of a practitioner who had finally advised operation. I was still unable to detect any tumour. On August 5th he was anæsthetised with chloroform by Mr. A. N. McArthur. Assisted by Dr. D. M. Morton I opened the upper abdomen in the middle line. The stomach was dilated but otherwise appeared to be free from disease. Further examination revealed a hard thickening of the third portion of the duodenum, with infiltration of the adjacent glands; above the thickened portion the bowel was dilated. It was decided to remove the growth. Sterile gauze, wet with hot sterile saline solution, was packed round; clamps were applied above and below the growth, and then rubber-covered Kocher's clamps on healthy bowel farther away. The intestine was divided between the clamps and removed with the affected gland *en masse*. Bleeding vessels were caught in compression forceps as they were cut and subsequently ligatured with silk. The cut edges were cleaned with dry sterile gauze and then approximated. A continuous silk suture was passed through all the coats, uniting the edges, some little difficulty being experienced owing to the difference of calibre. The line of union was then invaginated with another continuous silk suture—seromuscular where the bowel had a peritoneal coat and muscular only where there was no peritoneum on the posterior surfaces. The abdominal incision was united with interrupted silkworm-gut sutures, including skin, aponeurosis, and peritoneum. A high enema of one pint of saline solution and one ounce of brandy was given on the table.

The patient rallied well and had no vomiting. He was fed with saline and nutrient enemata alternately for the first 36 hours. Thereafter sterilised water, brandy and water, plasmon, peptonised broth, and milk were given by the mouth in amounts of half an ounce every two hours. The amounts were gradually increased and given at longer intervals. Alternate sutures were removed on the twelfth day and all the sutures on the sixteenth day, when the wound seemed to be firmly healed. On the twenty-first day, however, the scar yielded and some omentum protruded at the lower part. The wound was re-sutured and eventually healed firmly. The patient gradually gained strength, resumed his ordinary diet, and returned to his home in the country. On Oct 30th he came to town and saw me The scar was quite firm with no sign of hernia, he could eat ordinary diet with no discomfort, and his weight was 10 stones 2 pounds.

The following report was received from the pathological department of the University of Melbourne. "The specimen consists of a portion of duodenum about three and a half inches long. At its centre it is constricted and thi [illegible] and above this the bowel is dilated and shows signs of chronic irritation; below the intestine is normal. The strictured portion is one and a quarter inches long and its wall is three-eighths of an inch thick. It is of firm consistence and there is practically no ragged ulceration in lumen. The peritoneum is thickened over the growth and an enlarged gland is adherent to the peritoneal surface which is much wrinkled and looks as if numerous adhesions had been torn through. Microscopically the central thickened part is invaded with columnar carcinoma down to the circular muscular layer. On each side the carcinomatous infiltration extends, gradually diminishing as it is traced up and down until the muscularis mucosæ becomes intact. The carcinomatous tissue occurs in large masses with an attempt at alveolar formation. The central part of the stricture has no epithelium on the surface, which is formed of a band of fibrous tissue (with epithelial cells just below) The nuclei of the connective-tissue cells in this part are elongated, *indicating long-standing disease. The epithelial cells are of* a low cubical type and do not stain well. The vessels are not numerous and are fairly thick-walled, especially the inner coat The most noticeable point in the section is the great development of connective tissue, causing the firmness of the stricture and probably indicating relative chronicity."

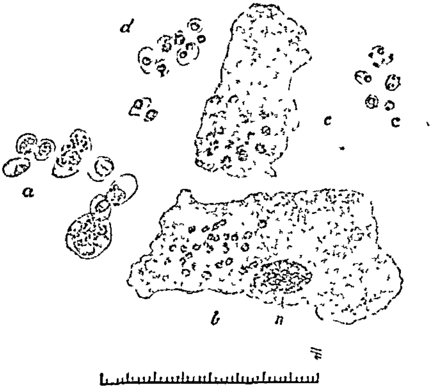
ON THE QUESTION OF TRYPANOSOMA INFECTION IN MAN.[1]

BY PROFESSOR F. MARCHAND,
OF LEIPSIC;
AND
J. C. G. LEDINGHAM, M.B, CH.B, B.SC, M.A.,
OF MARISCHAL COLLEGE, ABERDEEN.

THE articles of Leishman,[2] Donovan,[3] and Ross[4] prompt us to make the following communication. At a meeting of the Medical Society of Leipsic on Feb. 3rd, 1903, *there were exhibited by one of us (Professor* Marchand) microscopical preparations of the spleen, the liver, and the marrow from a peculiar case of splenomegaly accompanied by anæmia which was discussed in relation to the so called Banti's disease.[5] The case occurred in a man, aged 23 years, who had previously been quite strong and had taken part in the Chinese campaign. During the course of the war, however, and for eight months after its close he had enjoyed good health. About the end of January, 1902, he was taken ill in Leipsic, his complaint being loss of appetite and weakness. Towards the end of February attacks of headache and sweating began to intervene, occurring in a regular fashion every morning and afternoon. These symptoms were succeeded about the end of April by hoarseness and cough, for which he sought treatment in the clinic for diseases of the throat. Under *suspicion of malaria* the patient on June 7th was transferred to the Internal Medicine Clinic of Geheimrath. Professor Curschmann (St Jacob's Hospital). Here the presence of an already extreme enlargement of the spleen was verified (its length being 23 5 centimetres) Repeated examinations of the blood with a view to the discovery of malarial parasites were always followed by a negative result. *In the meantime* the patient suffered continually from fever which was partly of a remittent and partly of an intermittent character but conformed to no regular type. Further, severe anæmia and diarrhœa set in. In the beginning of August tubercle bacilli were found in the sputum, a phthisical process in the left lung gradually developed, cystitis intervened and death followed on Dec. 12th.

At the post-mortem examination, which was performed in the Pathological Institute, there were revealed advanced disintegration of the left lung, dysenteric and tuberculous ulcers in the large intestine, cystitis, pyelonephritis, and *an extreme enlargement of the spleen (length, 28 centimetres; breadth, 15 centimetres; weight, 1750 grammes).* The latter was somewhat soft and of a dark greyish red colour, changing in parts to a lighter hue. The liver showed a reddish-brown colour and slight enlargement and the bone marrow was red. Film preparations from the spleen were unfortunately not made and the examination of the blood from the cadaver showed, apart from the anæmia no important changes.

All the more surprising therefore was the result of the microscopical examination of sections of the spleen, the liver, and the marrow after fixation in Müller's fluid with 5 per cent. formol and hardening in alcohol. In the cells of the spleen pulp were found an extraordinary number of peculiar bodies of about 1µ to 1·5µ in diameter and which stained intensely with nuclear stains (hæmatoxylin, carbol fuchsin, &c) These bodies at first sight reminded one of micrococci but under the higher powers of the microscope presented themselves in the great majority of cases as distinctly ring-shaped. Some of the pulp cells showed rather advanced degeneration of their nuclei. The portal capillaries of the liver contained very *numerous large cells of an amœba type which in many cases* completely blocked the lumen of the vessel. These large cells possessed in their interior besides their nucleus proper a very large number of the same small bodies above described which frequently lay in larger clumps in vacuoles of the cell protoplasm. Very often, too, besides the small bodies the protoplasm of these large cells included leucocytes, sometimes not a few. The marrow likewise contained in addition to the usual marrow cells large numbers of the same huge amœba-like phagocytes which inclosed in their interior extraordinarily numerous small bodies of the same nature, as well as red blood corpuscles. It is to be noted, however, that the bodies were never found in the interior of the red blood corpuscles and that pigment formation was never associated with them Under high magnification the bodies exhibited surprisingly regular forms; the majority were of a signet-ring shape with a clear centre; in a large number of them there lay beside this ring shaped chromatin body a second and much more intensely stained (especially with carbol-fuchsin) dot of rounded or slightly elongated contour and which sat directly on the larger body or was separated therefrom by a small space. Generally this smaller body was situated with its long axis perpendicular to *the surface of the larger or sometimes also tangential to it.* Many of these bodies, and not only those lying in the cell vacuoles but also those which are to be found not infrequently lying free amongst the cells, were surrounded by a very fine faintly stained roundish or somewhat elongated halo of from 2µ to 3µ in diameter. (*Vide* diagram, copy of a drawing shown to the Leipsic Medical Society.)



Explanation of diagram —*a*, Several marrow cells (magnified 460 times). Some of the large cells contain the small ring-shaped bodies and one of them also contains vacuoles. *b* and *c*, Two large phagocytes from the marrow containing numerous bodies which show in part signs of rather severe degeneration (only a portion of the same is shown in the diagram). *d*, Several isolated bodies from the marrow with their inclosing halos. *e*, Similar ones from the spleen (from *b* to *e* magnified 1250 times). These bodies gave us the [illegible] familiar to us [illegible] like them bef[illegible] thing to do with malarial plasmodia proved quite unentertainable, when in support of it one had to consider the history of the *case as* well as the course of the fever, although certain doubts still remained as to whether some unknown form of malarial parasite, or, failing that, some quite strange protozoon, might possibly be present.

---

[1] Translation of [illegible]

For lack of some fixed starting point Professor Marchand in the above-cited address on Banti's Disease believed it incumbent upon him to give it as his opinion that the bodies represented the product of degenerated cell nuclei. For this view the appearance of the cells of the spleen pulp seemed specially to speak as in certain situations their nuclei presented a disintegration to all possible forms of granules and shreds of chromatin substance which exhibited apparently all transition stages to the ring-shaped bodies lying amongst them. Still, the discovery was characterised by Professor Marchand as a yet unsolved riddle. The condition of the marrow and liver where no signs of nuclear degeneration were present served always to cast doubt upon the view that the bodies might represent nuclear products; the oft-repeated and thorough examination of the bodies served to make their parasitic and protozoic nature still more certain. At the conference of the Deutscher Naturforscher und Aerzte in Cassel Professor Marchand demonstrated the bodies to the German Pathological Society on Sept. 25th, 1903, but none of those present could decide as to the nature of the bodies. So also Professor Korschelt and Professor Brauer in Marburg and Professor Chun in Leipsic, who were good enough to make a personal examination of the preparations, were unable to give a decided opinion. These gentlemen also had no doubt as to the parasitic nature of the bodies.

Unfortunately the cited communications in the *British Medical Journal* did not come to our knowledge till the end of November. The identity of the bodies found by Leishman in film preparations of the much enlarged spleen of a soldier who succumbed to a peculiar form of tropical fever in the cantonment of Dum Dum near Calcutta, with those discovered by Donovan of Madras in April, 1903, in film preparations of the spleen (three times post mortem and once after splenic puncture during life, later repeated) can no longer permit of doubt after Leishman's exact description. Demonstration of the bodies in sections seems generally to have met with failure, while in our case their demonstration presented no difficulties. Leishman is of opinion that the bodies found by him in the spleen pulp are degeneration forms of that species of trypanosomata which were first discovered in man not long previously by Dutton[6] in the case of a woman who had been infected in the Gambia region. He believes himself, therefore, forced to admit that trypanosoma disease occurs also in India, while this conclusion is still doubted by Donovan from the fact that no trypanosomata were found in the peripheral blood of the case examined by him during life. Leishman explains the appearance of the bodies in the following way. The trypanosomata lose their undulating membrane and the flagellum and only the shrunken macronucleus with the micronucleus remains behind. As a matter of fact, he was able to convince himself of the successive changes in this process after death in rats infected with Trypanosoma Brucei. Ross, as a result of his examination of Donovan's preparations, finds certain difficulties in accepting Leishman's view because, according to him, in the case in which remains of trypanosomata were concerned, at least isolated flagella must still have been present. Leishman[7] replies to Ross's objections on good grounds apparently. The reddish-stained rings round the chromatin body which were found in the preparations which Donovan made during life, and which gave support to the conclusion that these chromatin bodies were situated inside red blood corpuscles, might very well represent cysts or capsules. Still, up to the present Leishman considers it impossible to decide whether the small bodies are new parasites or really altered trypanosomes. Laveran,[8] who also had occasion to examine Donovan's preparations, believes that we have here to do with a new hæmatozoon which has no relation either to malaria or to trypanosoma and is to be referred to the genus piroplasma. He proposes the name piroplasma Donovani, but all the same gives the priority of the discovery to Leishman. (N.B.—The bodies were first described by Professor Marchand. We do not, however, lay great stress on this fact as Leishman has the honour of having recognised their relationship to trypanosoma.) Laveran found the parasites lying partly free and partly inclosed in red blood corpuscles. They were pear-shaped or oval, from 2·5 μ to 3 μ long and 1·5 μ broad, with a larger karyosome and a smaller accessory one which at times was joined on to the first by means of a short pedicle. The infected blood corpuscles, however, no longer stain like normal ones but are, as it were, washed out. These pale rings are surely identical with those above described in our case but which we could not recognise as being remains of red blood corpuscles but as constituent parts of the parasites themselves. Now, while we lay great value on the judgment of so great an authority on protozoa as Laveran we should not like to omit to mention in this connexion that Laveran and Mesnil themselves in their work on Trypanosoma Lewisi,[9] Plate XI, Figs. 10 and 15, describe changes in these parasites as a result of phagocytic inclusion by leucocytes which at least are very like those described by us. The slight difference in size (in Fig. 10) may well be due to an earlier stage in the change or to a difference in species. If then, as we consider probable, our case had also to do with a trypanosoma infection, we have certainly to admit that the infection took place during the patient's sojourn in China. On the strength of the correctness of the patient's history such a long latent period is certainly very extraordinary. On the other hand, the possibility of a like infection also in our neighbourhood (Leipsic) would not altogether be excluded although in the present case which occurred in winter it would be more than improbable. The case will be described in greater detail later.

The following additional facts relating to this important case have been ascertained quite recently by Professor Marchand. He says: "The stepfather of the deceased made in response to my inquiry the following important statements (which were in no way influenced by me). His son had been a soldier at Peking and had lain for a considerable period before the great walls. During the course of a long march he had received a fly bite on the foot, as a result of which his leg swelled enormously so that he could not draw on his boots and lay for about eight days in the lazaret. Of the further course of the illness nothing is known by his parents. On his return to Germany the deceased made a short stay of about three months as night watchman in the barracks in the vicinity of Leipsic, and though his disposition is said to have shown a change to a peevish morose type he was not considered to be really ill."

A CASE OF LOBAR PNEUMONIA IN WHICH THE PHYSICAL SIGNS PERSISTED FOR EIGHT WEEKS ACCOMPANIED BY A VERY IRREGULAR TEMPERATURE.

By J. M. BENNION, M.A., M.B., B.C. CANTAB.,
M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE PHYSICIAN TO THE METROPOLITAN HOSPITAL.

A WOMAN, aged 32 years, was admitted into the Metropolitan Hospital on June 8th, 1903. She was taken ill on June 3rd with a "shivering fit," severe headache, and pain in the right side. On the 4th she was feverish and was suffering from sharp pain in the side and cough. From this date until admission the temperature was high, up to 104° F. off and on. No phlegm was brought up. Her previous history was to the effect that she had ovariotomy performed 12 years previously and that she had suffered from pleurisy on the left side three months previously. Her parents were dead; one sister suffered from phthisis.

On June 8th she complained of great pain in the right side. She looked ill but was not cyanosed. Her temperature was 102·8° and her pulse rate was 120. Her respirations were 60 per minute and rapid and shallow. She coughed a good deal but brought up no phlegm. Her chest was of good shape moving rapidly, but the expansion of the right side was deficient. Her heart was natural. Examination of the lungs yielded the following results. On the left side the note was good; the breath sounds were vesicular and clear. On the right side in front there was impaired movement; the note was good over the upper three intercostal spaces but below it was much impaired. A friction rub was felt and heard in the third, fourth, and fifth spaces. Many crepitations were heard also in these spaces. On the right side behind the note was good; the breath sounds were vesicular over the upper two-thirds of the chest, but below the note was impaired and the breath sounds were weak. On auscultating the larynx expiration was noted to be much louder and longer than inspiration. The abdomen showed a linear scar of laparotomy but was otherwise natural. The urine was of specific gravity 1025 and acid; it yielded a slight cloud of albumin; the chlorides were diminished. On the 10th the patient remained much about the same as above described. In the morning she coughed up a little viscid phlegm (not rusty). Her temperature was 104°; her pulse and respirations were respectively 126 and 48 per minute. In her right chest in front there was less friction; behind, the note was much impaired over the base up to the mid-scapular region; loud bronchial breathing, bronchophony, and many crepitations were heard. On the 12th her temperature was 102 6°; her pulse and respirations were respectively 144 and 48 per minute. Over the right upper lobe behind the note was impaired and some crepitations were heard. On the 15th the patient was a little better in the morning, although the signs of consolidation of the right lung persisted. At 6 P.M. she was perspiring freely. Her temperature was 98 4°; her pulse and respirations were respectively 120 and 48 per minute. On the 25th it was noted that the temperature had not risen above normal since the 15th. Both lungs were now apparently clear in front. Behind on the right side the signs of consolidation still persisted over the upper half of the chest but the lung was resolving below; the note was good; some moist sounds were heard. On the 27th the cough was very troublesome. It was noted that the temperature rose on the previous night to 101°. On the 29th the temperature was high. Some crepitations were heard over the third and fourth right intercostal spaces after coughing, otherwise the physical signs were as noted on the 25th. On the 30th, just before 6 P.M., the patient had a rigor lasting about half an hour. Her temperature rose rapidly to 104° and her pulse and respirations were respectively 144 and 60 per minute. Her cough became frequent and distressing. On July 1st her morning temperature was normal but the signs of consolidation of the right upper lobe remained. From the 2nd to the 12th inclusive three grains of quinine were given nightly, while for the next three nights five grains of antipyrin were given. On the 6th it was noted that since the 1st a very irregular temperature had been present. On the previous night she shivered a short time before the temperature rose to 104°. The Widal reaction was found to be negative. The leucocyte count was 9800 per cubic millimetre. The condition of the right lung remained the same. On the 13th it was noted that every night the temperature ran rapidly up to 104° and that the patient usually had a slight shivering fit. On the 27th it was noted that the temperature had not risen above normal since the 23rd. The patient was now up half the day and was much stronger. The following physical signs were still present over the right upper lobe behind—namely, impaired note, vocal vibrations increased, bronchial breathing and many crepitations. On August 7th she left the hospital for a convalescent home, the temperature having been normal from July 21st. Her health has remained good since.

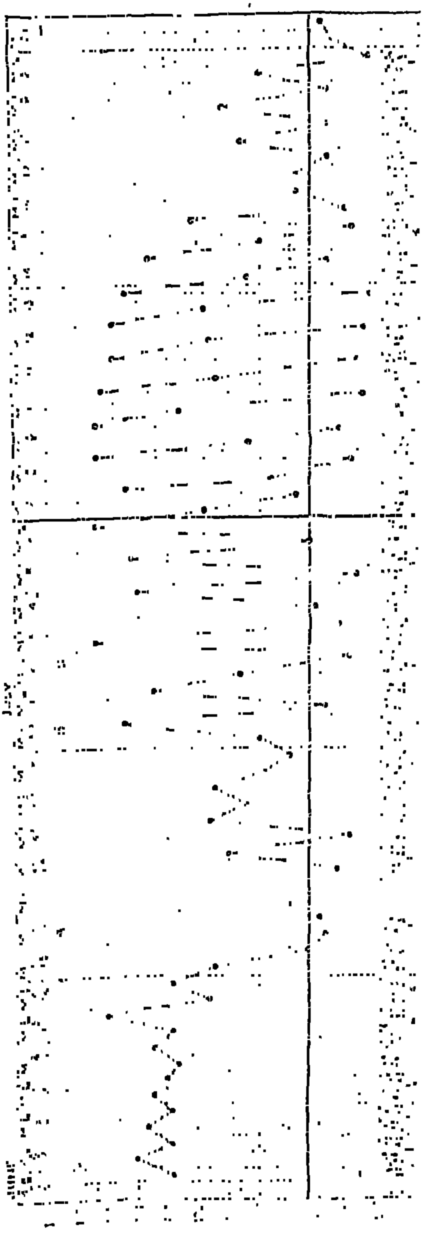
[8] Bulletin de l'Académie de Médecine, No. 35, 1903, p. 238.

[9] Annales de l'Institut Pasteur, 1901, vol. xv., p. 673.

The interest of this case, I think, lies in the rigors and the very irregular and high temperature which occurred ten days after the temperature had been normal, and also in the length of time taken by the right lung in resolving. The temperature chart and rigors suggested that the patient was suffering from septic absorption from a collection of pus somewhere. The chest was constantly examined for any signs of fluid. Empyema was of course, thought of, but as no physical signs of fluid were found a needle was not put into either pleural cavity. A leucocyte count on July 6th and 14th proved to be about 10 000 per cubic millimetre. This fact was not in favour of a collection of pus being the cause of [illegible] Empyema was therefore co[illegible] not the cause of the pa[illegible] amily history of phthisis and acute tuberculo-pneumonic phthisis was thought to be the most likely diagnosis, and in consequence a very unfavourable prognosis was formed. As there was no sputum the diagnosis could not be confirmed. The Widal reaction was negative and typhoid fever was therefore excluded. The diagnosis of acute tuberculo-pneumonic phthisis evidently was wrong. The rigors and very erratic temperature from June 30th to July 16th were therefore probably due to



A, The temperature remained normal until June 26th. B, Rigor.

the absorption of toxins from the delayed resolution of the right lung. I have to thank Dr. Arthur T. Davies (under whose care the patient was in the hospital) for permission to publish the case.

Petersfield.

ATMOSPHERIC TEMPERATURE AND SMALL-POX.

BY DAVID SIVEWRIGHT, M.A., M.B., CH.B., D.P.H. ABERD.

IT is generally recognised, I think, that there is some connexion between the atmospheric temperature and the incidence of small-pox cases. During the epidemic in London in the winter 1901–02 I collected from the *Standard* a series of statistics from which I have made calculations bearing on the point. I have taken weekly averages of the maximum shade temperature and the minimum shade temperature, also similar averages of the admissions of cases to the hospitals of the Metropolitan Asylums Board. Allowing 12 days for incubation and an average of two days for the cases to be recognised and sent off I have compared the averages of temperature of one week with those of the admissions on the third week following I find on putting these numbers on charts that a rise in the number of cases generally corresponds with a fall in temperature, and *vice versâ*. The correspondence of each rise in the number of cases with a fall in temperature is not absolute, at the same time I think it is sufficient to warrant the assumption that the relation is more than a casual one. I have also in the same way compared the maximum solar radiation in vacuo with the cases admitted and find that the correspondence is even more striking in this case. The accompanying charts illustrate the article.

Catford, S.E.

CHART 1.

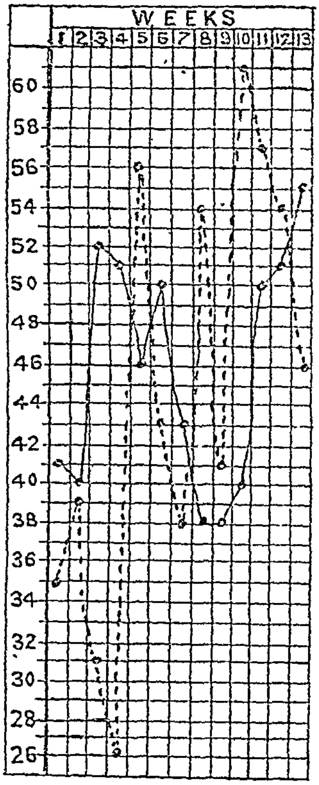


CHART 2.

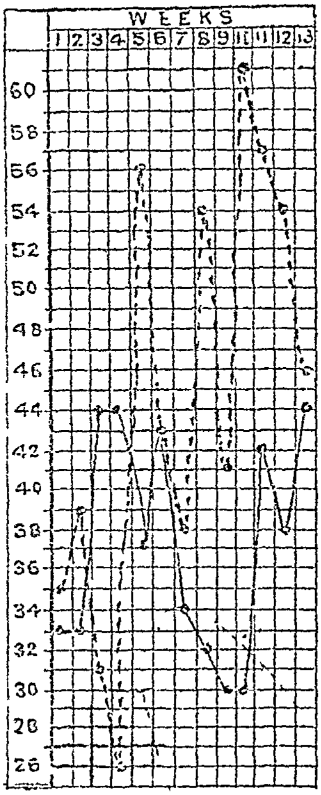

CHART 3.

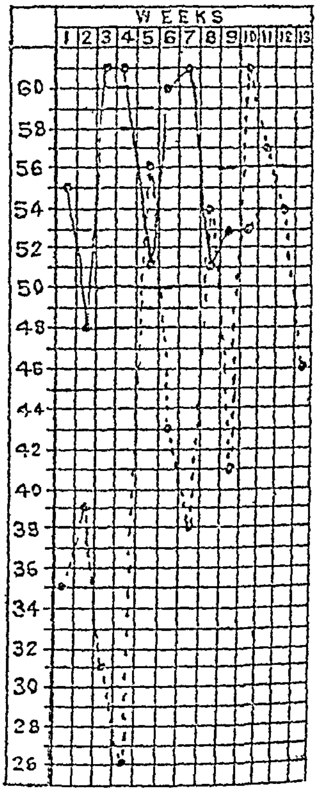

The dotted line in all the charts denotes small-pox cases (first week commences Dec 28th, 1901) In Chart I. the continuous line denotes the maximum and in Chart II. the minimum shade temperature in degrees Fahrenheit (first week commences Dec 14th, 1901). In Chart III. the continuous line denotes the maximum solar radiation in vacuo in degrees Fahrenheit (first week commences Dec. 14th, 1901). The temperature curve for the last three weeks is not given because it rose to 77°, extending beyond the limits of the chart.

CASE OF RUPTURE OF THE LEFT AURICLE.

BY F. W. FOOTT, L.R.C.S., L.R.C.P. IREL.,

WITH A NOTE

BY F. DE HAVILLAND HALL, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE WESTMINSTER HOSPITAL.

I WAS called to a man, an Arab, aged about 40 years, a stoker on the P. and O. line of very fine muscular development. There was a history of his having been in a Bombay hospital two years previously for "something." On my arrival I found that he was dead, having fallen "all of a heap." Previously to the fall he had been playing a game of cards. The game over, he rose suddenly to see if his supper was being cooked, when he fell, as described, in the kitchen.

I suspected aneurysm and by the coroner's order made a post-mortem examination in the presence of two other qualified men and we found the following conditions present. The pericardium was full of blood (*none being outside the pericardium*), the left ventricle was hypertrophied, the auriculo-ventricular ring was stretched, the mitral valve was not nodular and was apparently healthy, the wall of the left auricle was exceedingly thin and stretched, and there was a small tear about half an inch in extent on the outer and posterior surface, the thinnest part. The muscular substance of the heart looked fatty—i.e., it was pale in colour and not firm. A microscopical examination was not made. The pulmonary and general venous systems were loaded with blood. The kidneys were very lobulated but otherwise normal.

The etiology appears to be as follows. The man was a ship's stoker, a notoriously laborious occupation and one throwing great strain on the heart; this caused the hypertrophy and dilatation of the left ventricle, with the usual sequence of incompetence of the mitral valve and secondary dilatation of the left auricle from overfilling during ventricular systole. Possibly the site of rupture was a particularly weak spot where the backward stream of blood impinged on the auricular wall.

Remarks by Dr. DE HAVILLAND HALL.—The occurrence of rupture of the heart, and especially of the left auricle, is such a rare event that I induced my friend Mr. Foott to place on record this extremely interesting case. The statistics that have been collected on the subject show that in 77 per cent. of the cases of rupture of the heart (excluding cases of traumatism) the rent takes place in the left ventricle, in 14 per cent. in the right ventricle, in 6 per cent. in the right auricle, and in the remaining 3 per cent. in the left auricle. So that the case under consideration belongs to the rarest form of rupture of the heart. As is usually the case, the rupture occurred in a man, but at a much earlier period of life than is common. According to Walshe, "rupture of the heart is favoured by advanced age; it becomes comparatively frequent after the fiftieth, still more so after the sixtieth year." Out of 100 cases collected by Quain in 12 the rupture took place under the age of 50 years and two of these occurred between the ages of ten and 20 years, so that while rupture is very uncommon in early life the possibility of its occurrence should be borne in mind.

Though the authorities whom I have consulted do not appear to lay stress on a laborious occupation as a factor in the production of rupture I think that there is much cogency in the explanation given by Mr. Foott of the cause in his case. Unfortunately, a microscopical examination of the heart muscle was not made, but the naked eye appearance was in favour of fatty degeneration. Gowers in his article on Fatty Diseases of the Heart in Reynolds's "System of Medicine" says emphatically: "Spontaneous rupture never occurs in a healthy heart," and it is "probable that in at least nine tenths of the cases of rupture fatty degeneration is the condition of the cardiac wall to which the accident is due."

The mode of onset varies very much; sometimes the rupture is induced by physical exertion or great mental excitement. Of 24 cases collected by Barth, in five death occurred during the act of defecation. It may occur during sleep, as in a case of spontaneous rupture of the left auricle reported by Dr. M. Mackintosh.[1] In the classical case of George II., who died from rupture of the right ventricle, it is stated that he rose at his usual hour of six, drank his chocolate, inquired how the wind was, being anxious for the arrival of the mails, and then suddenly fell, uttered a groan and expired.

In Mr Foott's case there was neither mental nor physical excitement to account for the rupture and there were no premonitory symptoms as sometimes happens. In Dr. Mackintosh's case, for instance, the man complained of pain in the epigastrium in the evening which he attributed to his having had a dinner of hard, badly-cooked beef. He died the same night in his sleep. As Dr. Mackintosh points out, the marked ecchymosis which was found in the neighbourhood of the rent in the left auricle suggests that some laceration took place during his work, causing the pain he complained of, and that the final rupture occurred during sleep, the result being instant death.

NOTES AND COMMENTS UPON FIVE CASES IN WHICH CHLOROFORM ANÆSTHESIA WAS CARRIED OUT BY DUBOIS'S APPARATUS.

BY P. M. CHAPMAN, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE HEREFORDSHIRE GENERAL HOSPITAL.

THE induction of anæsthesia by chloroform has fallen into much discredit, although its use is persisted in and ably advocated by some of us. Certain advantages connected with it lead perhaps most of us to regret that we are obliged to abandon its use. Although complete anæsthesia can be induced by ether in less than three minutes and the irritation and distress often caused by it can be avoided to a great extent by the previous administration of nitrous oxide gas, we seem still to be out of our path and away from perfection. All is vague and haphazard. With ether even young girls may become violent and inebriated and may require large quantities. The profuse frothy mucous secretion and salivation may often cause infinite trouble and some anxiety, and the occasional evil after-effects are known to all.

To the administrator, the anæsthetic employed has mainly to be considered in the two aspects of its chemical and physical properties. The one, however inseparable from the clinical aspect, should be first considered by the physiologist who should furnish us with some certain data for our guidance. The physical problem should never be lost sight of by the administrator himself and is to some extent his to consider. 1. The chemical problem involves a study of the effects of toxic vapours upon nerve. Of these effects we have gained in late years some definite knowledge through the labours of Dr. A. D. Waller. Briefly, nerve resumes its normal reactions after loss of function from exposure to 1 0 to 2·0 per cent. chloroform vapour. By a small excess beyond this nerve may be poisoned and with larger doses it will certainly be poisoned beyond recovery. 2. The physical properties of chloroform make it a grave source of danger It is customary to use it by the "open method," a small but unmeasured quantity being poured upon lint which is held in the hand at some variable distance from the face Owing to its high specific gravity the vapour falls in a downward stream, and the approximating of the hand to the face may rapidly raise the percentage inhaled to four or five times beyond the limit of safety. In labour, where chloroform is frequently used and with few accidents, the patient is usually lying on her side, and this permits the vapour to stream past the face, much of it being thus happily wasted. Moreover, the quantity used is but small. The senses are but dulled and complete anæsthesia is neither sought for nor desirable.

No apparatus giving a constant supply of a definite percentage of chloroform vapour is in ordinary use The Junker inhaler is a notable endeavour in this direction, though it cannot be granted that it supplies a definite and accurate percentage nor that it allows perfect freedom of expiration Dr Waller having lately deeply interested me in the method of anæsthesia practised in the physiological laboratory at the University of London (whereby an accurate percentage of chloroform vapour is supplied in a constant stream, the expiration being unimpeded) I obtained the consent of my surgical colleagues on the staff of the Herefordshire General Hospital to use his apparatus on one of their operating days upon a small series of unselected cases occurring in the ordinary course of their work. The anæsthetic was administered by Dr. Waller himself while I closely watched the cases and took notes of their condition.

CASE 1. *Sacro iliac disease; psoas abscess*—The patient was a young adult. At 1.23 P.M. the administration was begun, 1 2 per cent of chloroform. 1 24, increased to 2 per cent. 1 31½, diminished to 1·2 per cent. 1.33, abolition of the conjunctival reflex (ten minutes after commencement). 1 34, operation commenced. 1 37, slight vomiting and retching, administration discontinued for about half a minute. 1 37½, increased percentage to 2 per cent. 1 40, operation completed; administration discontinued. The patient first spoke nine minutes after leaving the theatre. She vomited at 4 25, at 6, and at 6 50 slightly. She had had ether on a former occasion and of the two rather preferred ether.

CASE 2 *Excision of hydrocele.*—The patient was a labourer. At 1 47 P M administration was begun; 2 per cent. chloroform was continued throughout. 1 52, stage of excitement and muscular resistance; the patient was talking loudly; pulse rate 150 1 55, excitement passing off; pulse-rate 80. 1.56½, complete anæsthesia (nine and a half minutes from commencement). 1 57, operation begun; slight movement at initial incision; still muttering incoherently. 1 59, silence; pulse-rate 108 2 0, slight stertor; faceplece removed for one or two respirations. 2 2, rather increased stertor. 2 4, quite quiet and breathing easily; pulse rate 108; respirations 44. 2.7, stitches being inserted, no sign of movement. 2 9, administration discontinued. 2 11, sleeping quietly; no conjunctival reflex; pulse-rate 92. 2 14, dressing completed, pulse-rate 128. 2 15, answered to name and responded not quite incoherently to questions.

CASE 3 *Operation for varicose veins.*—The patient was a labourer. At 2.20 P.M. administration was begun; 2 per cent. chloroform. The pulse rate was 96 2.23, stage of excitement. 2 26, conjunctival reflex abolished. 2.28, operation began; no movements. 2 38, operation over; administration discontinued. 2.40, conscious of questions; incoherent in reply.

---

[1] THE LANCET, Feb. 1st, 1890, p. 239.

CASE 4 *Operation for removal of cervical glands.*—The patient was a female adult. At 2 48 P.M. administration was begun; 2 per cent. chloroform. 2 54, conjunctival reflex abolished; complete anæsthesia. 2.56, operation began; no reaction to incisions from beginning, no struggling, and no stertor. 3 6, retching, slightly vomiting. 3 16, reduced to 1·2 per cent. chloroform. 3.21, stitches being inserted; no movement. 3 27, operation over; administration discontinued. 3 32, slight retching. The patient first spoke at 3.55. She vomited at 4 20 and at 5 30. She said that she thought (having had chloroform once before some ten years ago) that this time "it was longer in taking and not so strong," she "felt nothing," she "was more sick last time," and "liked this much better."

CASE 5. *Circumcision.*—The patient was a baby, aged three months (?). At 3.35 P M. administration was begun; 2 per cent. chloroform. 3.38, reflexes abolished; slight movements on removing the prepuce. 3.40½, administration discontinued; all quiet.

Throughout the whole series I was greatly struck with what I must call the maintenance of the anæsthesia upon a smooth plane below the surface of consciousness. Though sunk to a depth beyond sense each case attained a certain level of rest not beyond our reach, neither occasionally rising therefrom nor sinking into any deep and perilous pool. The administration being discontinued each patient quickly rose again to the surface of consciousness. Throughout there was quite an extraordinary absence of anxiety, and I am clear that this feeling was produced through my observation of the patient's real condition under the anæsthetic and was not unduly owing to the fact that for the first time in my experience I knew with some approach to accuracy what was being done. Case 4 had some years previously taken chloroform for the same kind of operation. On this, the later, occasion she was completely under its influence to the full surgical degree for 33 minutes when the administration was discontinued. She could speak 27 minutes afterwards. The next day I asked her to compare her sensations on the two occasions. She said "it was longer in taking and was not so strong." On this last occasion she "felt nothing"; she was "more sick the other time," and "liked this much better." For myself I should without hesitation choose this means if I had again to undergo a surgical operation.

There are few practical difficulties. The use of the apparatus necessitates the turning of a handle attached to a small wheel at the rate of about four revolutions per minute. This can be done by the administrator almost mechanically. But it is better that he should have both hands free and the whole of his attention disengaged. The wheel can be turned by anybody, for it requires no skill and it can be done at a distance from the operating table. It could be worked by a motor or with a treadle by means of some suitable adjustment. By whatever means the stream of vapour is supplied to the facepiece the administration itself is of the utmost simplicity. There is free exit from the facepiece for all expired air and if the chloroform vapour, always of known strength, is supplied in greater abundance than is necessary, it merely passes harmlessly out of the orifices in the facepiece and is not pumped into the lungs. The patient has absolutely no sense of there being any obstruction to his breathing. He is simply inspiring air mixed with chloroform vapour to the extent of 2 per cent. or *under*, and this maximum quantity cannot be exceeded through any over-zeal on the part of the person, however untutored he may be, who is turning the handle. Excess of zeal means waste of vapour at 2 per cent, no greater percentage can possibly be inspired. The machine itself cannot supply a higher percentage without active interference on the part of the administrator.

I am not surprised to learn that animals can breathe such an atmosphere and remain completely unconscious for many hours at a time without ill-effects. I myself have exhibited it to a cat for several hours and have witnessed the animal lf an hour afterwards lapping milk, purring happily, and bing itself affectionately against my legs. I am led to of its possible use in the future in cases other than of surgical operation. Some may think that the time occupied in inducing anæsthesia is too long. It is not, for adults, apparently less than six, nor more than ten, minutes. But rapid anæsthesia has been pushed to a point which has roused some protest. These protests might be ignored if the rapid induction of anæsthesia were wholly safe and pleasurable. Since it is not so, and since inhalation as now practised is nearly always very disagreeable and is often terrifying to patients, being a considerable addition to their already pitiable anxieties, I feel that we ought not to deny them this easy and pleasant means of relief. For to say the least we cannot plead that this method is less safe; nor do I see that we have any excuse for not admitting it into our daily hospital practice unless we are prepared to plead against it some small considerations which merely affect our own convenience. But all undue advocacy is to be avoided. The important matter in this connexion is our *clinical* experience of the method, and at this early stage of our experience it is essential that *every case* in which the method has been applied should be reported without selection, or omission of favourable or unfavourable features, or of actual failures if such should occur.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF ERYTHROMELALGIA.

By BRUCE C. KELLY, M.B., C.M. EDIN., M.R.C.S. E

VARIOUS theories have been advanced to explain the g
of symptoms known as erythromelalgia—e.g, the
that it is due to a neurosis, to a peripheral nerve
to a spinal lesion, to a cerebral lesion, and to a
lesion. The case about to be described, thou
because there was no necropsy, would seem
spinal lesion, as do many other recorded cas
of this disease being due to a spinal lesion
that it coexists with tabes dorsalis, disseminat
spinal tumours, general paralysis, and other co
like kind. The secretory and vaso-motor tro
example, syringomyelia have their seat in the
of the cord in its middle part adjoining the
posterior cornua. Cases have been described
peripheral nerves have been found unaffected.

The following is the history of a case occ
married woman, 77 years of age, who had
neurotic troubles, who had advanced arterial d
who had had three attacks of hemiparesis, and
symptoms or physical signs pointing to affection
pheral nerves. She began to suffer from eryt
in October, 1901 She had a left-sided hemipa
before. There was no exciting cause, remote
her history. The illness began with severe
shooting" pain in the outer part of the left f
panied by redness and swelling of this part of the
pain was paroxysmal, and the intervals of freedom
became shorter and the paroxysms more severe.
weeks there appeared swollen, purplish-red patc
inner part of the sole and on the heel. The supe
of the foot, on the dorsal and plantar aspects, an
were markedly swollen. The surface temperatu
but pulsation could not be felt. The pain soon ex
the knee and the whole foot sweated
was aggravated by hanging the foot, so that
bear to stand, and was temporarily relieved by

oles. The pain became almost constant and she died, n out, nine months from the commencement of her ess. Unfortunately, no post-mortem examination was mitted.

rythromelalgia is an affection of the vaso-motor system, ably of the vaso-motor centres in the spinal cord—either over-action of vaso-dilator or a paralysis of vaso-con-ctor centres. Are there any means of localising the lesion e definitely? It has recently been shown by Laignel-astine[1] that by destroying the sympathetic cord in the le length of the thorax of dogs and keeping the animals e for some months there were produced spinal lesions, ecially evident in the cells of the base of the anterior u and in the lateral cornu. This writer thinks it able *that the efferent fibres of the sympathetic have* the most part their origin in the cells of the lateral nua. In the *Revue de Médecine* for October, 1903, there hat appears to be clinical confirmation of this research the publication by Lannois and Porot of a case of hromelalgia, the spinal cord in which actually pre-ed lesions of these parts. A widow, aged 55 years, wed vaso-motor phenomena of the fingers of the left d immediately after the death of her husband. Five ks later she had a monoplegia of the left arm wn by necropsy to be due to cortical softening). The emities of the fingers were swollen like drumsticks the nails were thin and grooved. A few weeks later hand became cold and she had patches of gangrene the toes. Post mortem the left crossed pyramidal and right direct pyramidal tracts were degenerated. There atrophy of the left half of the grey matter of the cord, cting especially the anterior cornu in the cervical and sal regions. There was much diminution of the pro-ence that the lateral cornu gives ordinarily to the outer der of the grey matter. In the dorsal region there was ost complete disappearance of the lateral cornu and its s, there being only two or three atrophied cells present— atrophy of the *intermedio-lateral tract; there was* atrophy, indeed almost complete disappearance, of the umn of small fusiform cells that normally exists at the the posterior cornu. Clarke's columns were intact. cervical region there was atrophy of the cells repre- the upward continuation of the intermedio-lateral .e., the antero-lateral group of cells of the anterior This atrophy of the intermedio-lateral tract was pre-oughout the upper dorsal cord and was out of all pro- more marked than the atrophy of the rest of the grey The arteries of the cord were in a state of advanced ration. No lesions of peripheral nerves were found some sheaths empty of myelin but containing intact ylinders. If these researches, experimental and , are confirmed it will be possible to localise the otor lesions of erythromelalgia in the cells of the edio-lateral tract and in the small *fusiform cells at* se of the posterior cornu. It is not necessary to point e significance of the vascular degeneration in the n such cases.

Somerset.

ON A CASE OF CHANCRE OF THE LIP AND ITS MODE OF INFECTION.

LEOPOLD G. HILL, M.R.C.S. ENG., L.R.C.P. LOND.,
ITAL OFFICER, CHURCH MISSION HOSPITAL, PAKHOI, SOUTH CHINA.

RING the past year a couple of well-marked cases ancre of the lip have come under my notice in the n hospital here, one of which has such a clear history origin that it is worth recording.

male Chinese, aged 24 years, came to the mission tal, on March 17th with an ulcer almost in the e of his upper lip; it was very painful and partly ed with a blood scab. He had had it for about a night, but the day before it was more painful, so he ght relief. The ulcer was of the size of a split pea and the so-call- It was not ising much held stiffly. ere were tw isible, that the left being of the size of a small nut and that on right, the larger, that of a filbert. It was undoubtedly hancre. It is unnecessary to go into the after-history except to say that under mercury by the mouth and inunction the chancre and enlarged glands disappeared and that the patient regained his usual health as soon as the debilitating effects of the drug passed off and also that 11 weeks after the onset of the disease he had some suspicious symptoms of secondary syphilis—feverishness, pains in the bones, and slight sore throat—which soon cleared up and now he is in excellent health.

The point of interest is how he contracted the sore His only child, some eight or nine months old, was being treated a month or so before and was then under treatment for congenital syphilis, consisting chiefly in a running at the nose, "snuffles," and emaciation—at that time beginning to improve and now a strong enough looking child. His wife—*he married a widow—had had syphilis ten years ago*, contracted, presumably, from her first husband; by him she had become pregnant twice and had had two miscarriages, carrying the fœtus nearer to term each time, but not a living child by him. The first child by the second husband was born dead at full term; the second, a puny child at birth, is the one referred to as having the nasal discharge. The father is extremely proud and fond of this child and I had often seen him nursing it in its sickness, kissing it and fondling it with his mouth on the child's face in spite of the moisture coming from the nose. No doubt some of this infected a scratch or open sore on the delicate lip and produced the chancre.

Pakhoi.

SYMPTOMS OF SUFFOCATION IN AN INFANT CAUSED BY A PIECE OF COAL LODGED IN THE TRACHEA; OPERATION; RECOVERY.[1]

BY WALKER DOWNIE, M.B., C.M., F.F.P.S. GLASG.,
LECTURER ON DISEASES OF THE THROAT AND NOSE, GLASGOW UNIVERSITY AND WESTERN INFIRMARY.

ON Nov. 11th, 1903, an infant boy, aged 15 months, was left to play in the kitchen while his mother did some work in the washhouse. When his mother returned she found him sitting on the floor near to the fireplace. He was crying and gasping for breath, with the fingers of both hands in his mouth. The mother concluded that the child had put some of the cinders which were lying on the hearth in his mouth and that possibly he had swallowed some. During the rest of the day the child was very fretful, had considerable difficulty in breathing, would take no food, and frequently cried as if suffering pain. day there was a stead When the medical r suffering from what he considered to be laryngeal obstruction, and without delay had the child sent from the country to the Western Infirmary as an urgent case. The child was admitted late in the evening of Nov. 12th and was seen by me about 10 P.M. He was then pale and exhausted and while suffering from severe dyspnœa had no hoarseness—his cry was perfectly clear. The pulse was 148 per minute, the respirations were 64 per minute, and the temperature (which was taken with difficulty on account of his struggles for breath) was 100 4° F. The marked indrawing of the intercostals and the epigastrium was an index to the serious nature of the obstructive difficulty present. By auscultation it was found that the amount of air entering the lungs was greatly deficient, that both sides were equally affected, and that the respiratory murmur, particularly towards the bases, was accompanied by mucous râles. The cause of the obstruction to the entrance of air was evidently in the trachea and probably was well down in that tube. An examination by the x rays gave no sign of the lodgment of a foreign body.

For the removal of the foreign body, the presence of which was indicated by the history and the symptoms, inversion was first tried but without benefit. The child was then placed under chloroform. The larynx was inspected with the laryngoscope and found to be normal, after which tracheotomy was performed. When the tracheal cartilages were split and the edges of the incision held apart a black object, lying transversely and firmly fixed within the trachea, was seen at the level of the fourth ring. This was grasped with forceps and removed and it was found to be a piece of coal measuring half an inch long, by three-sixteenths of an inch broad, and one-eighth of an inch thick. A tube was inserted lest any fragments might have been broken off and retained. As soon as the piece of coal was removed the child breathed with freedom, the chest expanded fully, and the child was asleep shortly after. Later, he again became restless and his temperature at 4 A.M. was 101·8°, his respirations were 58, and his pulse was 144 per minute. At 8 A.M. on the 13th his temperature was 100·6°, his respirations were 46, his pulse was 136, and at 10 A.M. the tube was removed. From this time there was a gradual but steady improvement and on the 15th the evening temperature was 98·4°, the respirations were 28, and the pulse was 124. The child is now well and the wound healed.

ST. THOMAS'S HOSPITAL.

SEVEN CASES OF INTESTINAL OBSTRUCTION.

(Under the care of Mr. G. H. MAKINS, C.B.)

THE following seven cases of intestinal obstruction seem worthy of brief record, since, besides possessing some surgical interest, no less than six of them, illustrating most of the more common causes of the condition, were met with during the course of a single major week at St. Thomas's Hospital. The first case which is added as affording an example of one other cause was admitted in the preceding major week.

CASE 1. *Cæcal volvulus.*—The patient was a woman, 67 years of age. During the last 18 months she had been the subject of four or five distinct attacks of abdominal pain accompanied by vomiting sufficiently severe to confine her to bed. Ten days prior to her admission to hospital she was seized with severe pain in the lower abdomen, most acute in the region of the umbilicus. Obstruction of the bowels had been complete for six days, vomiting had been frequent, and neither flatus nor fæces had been passed per rectum. On admission the woman looked anxious and ill; vomiting of dark feculent smelling fluid was frequent. Constipation was absolute. Her tongue was furred but not very dry. Her pulse-rate was 108 and her temperature was 97° F. Her abdomen was considerably distended; the prominence was median and on inspection gave the impression of a tumour rising from the pelvis. It was resonant throughout except in the right flank.

An operation having been decided upon, the abdomen was opened through the right rectus from just above the level of the umbilicus downwards. A hugely ballooned piece of bowel was at once disclosed occupying the whole field of operation. The incision was enlarged but the distended gut could not be delivered as it was tightly wedged into the pelvis. A trocar and cannula were therefore introduced and a large quantity of gas and liquid fæces was evacuated. The slackening of the tumour thus produced allowed of the hand being inserted into the pelvis beneath the sac and the piece of bowel was brought out. The intestine affected proved to be the cæcum and lower part of the ascending colon which was provided with an unusually long mesentery. The twist was through half a circle and involved the ascending colon about the centre of its length. The ileum remained viable. It was considered advisable completely to empty the loaded bowel which was then readily replaced, the two punctures having been securely sutured. The patient made an uneventful recovery, the bowels acted spontaneously the day after the operation, and the stitches were removed from the abdominal wound on the eighth day. On the fourteenth day a localised collection of pus was evacuated from the lower part of the wound in the abdominal wall and at the end of a month the patient left the hospital recovered.

CASE 2. *Carcinoma of the rectum.*—The patient was a man, aged 43 years, with a history of chronic constipation which had existed for years and for the last two months was much aggravated and accompanied by abdominal pain. There was no history of passage of blood or mucus. On examination the abdomen was found to be highly distended, visible peristalsis being marked. On introduction of the finger into the rectum a growth was discovered extending within three inches of the anus and firmly fixed. Inguinal colotomy was performed and three weeks later the patient was transferred as "relieved" to Lambeth Infirmary.

CASE 3. *Persistent Meckel's diverticulum.*—The patient was a man, aged 41 years, who had not had any intestinal trouble until seven years ago, but since then had suffered from attacks of abdominal pain once or twice each year. These attacks were sometimes accompanied by vomiting but never by any marked constipation or diarrhœa. They were of sufficient severity to oblige him to discontinue his work as a clerk for a few days. Three days before admission a similar attack of pain occurred; it was of a gnawing character, never very severe, but was continuous and seemed to spread across the abdomen just below the level of the umbilicus. Vomiting persisted throughout and at the time of admission the bowels had not acted for four days. The abdomen was moderately distended; the tongue was moist; the pulse was 75 per minute, regular, and of fair strength; and the temperature was 98° F.

A three-inch incision was made through the right rectus, starting just above the level of the umbilicus. Collapsed gut was at once discovered in the pelvis and when followed up led to a band stretching from the ileum to the umbilicus. This was at once recognised as a broad Meckel's diverticulum. The distal end was freed from the umbilical attachment and the strangulation was relieved. The constricted part of the bowel was in good condition. The diverticulum was removed and the abdomen was closed. The patient made an uneventful recovery and left the hospital on the seventeenth day well. The diverticulum was a broad one with a lumen at the distal end at least one inch in diameter. It may be mentioned as a matter of interest that the solitary follicles in this part were enlarged and inflamed but no ulceration had taken place. In a former case published by Mr. Makins the diverticulum was riddled with perforations which he thought might be the result of previous follicular inflammation.

CASE 4. *Intestinal adhesions.*—The patient was a man, aged 21 years, who 12 years before admission had been stabbed in the left half of the epigastric region. Three weeks before admission he felt himself unwell, the motions were very offensive, at times he vomited, and on one occasion the matter was said to be feculent. During this period the bowels were irregular, constipation for as much as four days alternating with days on which the bowels were opened by enemata. On admission the bowels had not acted for some days; the tongue was dry and brown; the pulse was feeble and 84 per minute; and the temperature was 97° F. The abdomen was not distended but marked peristalsis was observed around the umbilicus; the walls moved well. Nothing abnormal was discovered on palpation and there was resonance throughout. From the history and the general condition of the patient it was evident that the illness had commenced as a gastro-enteritis, followed by intestinal toxæmia. It seemed not the less clear that considerable obstruction existed in the course of the small intestine and an exploration was decided upon.

In spite of the cicatrix in the upper part of the left rectus over the cardiac end of the stomach it was thought better to make an incision through the right rectus, the centre of which corresponded with the level of the umbilicus, as it appeared unlikely that small intestine could be implicated at so high a level as the scar. This proved a considerable convenience, since the relation of the intestine to the scar which was after all found to exist was able to be investigated thoroughly and the danger of cutting directly down on adherent intestine was avoided. The jejunum was found attached to the scar and sharply kinked, dilated above the kink and considerably contracted below it. The adhesion was freed and the abdomen was closed. The after-progress of the patient was slow. For 12 days he lay with a sunken face, dark rings around his eyes, and mentally much depressed. The bowels acted freely, on several days the condition amounting to severe diarrhœa; the pulse remained of poor quality, usually about 80 per minute; and the temperature was normal or subnormal. Nourishment was taken badly but there was no sickness. Neither the administration of purgatives nor of salol as an intestinal antiseptic appeared materially to influence the condition. The stitches were removed from the wounds on the eighth day, when they appeared soundly healed. On the fourteenth day the temperature rose above 100° and on examination of the wounds the one through the old cicatrix was [illegible] was opened up at its superior end [illegible] from this wound for the next 1[illegible] the patient steadily improved, and on the thirty-first day he was discharged as well.

CASE 5. *Obstruction of the small intestine by an adherent vermiform appendix.*—The patient was a female, seven years of age, and was admitted with a history of six days' abdominal pain accompanied by vomiting and absolute constipation. She complained much of pain in the lower abdomen but tenderness was neither acute nor localised The abdomen was moderately distended, resistant to palpation but not rigid, and respiratory movement was fair. Her temperature was normal and her pulse rate was 114, rising to 120 at the time of the operation. Mr. P. W. G. Sargent opened the abdomen for Mr. Makins. An incision was made through the right rectus; on opening the abdomen a small quantity of clear fluid escaped, the upper part of the small intestine was much dilated, and below this a loop was found strangulated (not tightly) behind the vermiform appendix which was bulbous at its extremity and was adherent to the anterior abdominal wall. The bowel was readily released and the appendix was freed from the abdominal wall and removed. The child made an uninterrupted recovery and left the hospital on the twenty-first day.

CASE 6. *Ileo-cæcal intussusception.*—The patient was a female, aged eight months, a breast-fed child and with no history of anything solid having been swallowed. She awoke screaming one day at 5.30 A.M., a green motion was passed, and at 9 A.M. blood and mucus were passed. At 1.30 P.M. Mr. Wallace opened the abdomen for Mr. Makins and reduced the intussusception. The infant made an uninterrupted recovery and left the hospital well at the end of 14 days.

CASE 7. *Carcinoma of the ascending colon, with incomplete obstruction*—The patient was a woman, aged 41 years. For nine months previously to admission she had not been in her usual health. She had noticed tenderness and swelling of the abdomen and three months before admission she had had two severe attacks of abdominal pain. This pain was very severe, colicky in character, "doubling her up," and was situated just above the umbilicus. Other attacks of a similar nature followed at short intervals and the more recent ones were accompanied by vomiting starting about six hours after the initial attack. Slight transient constipation followed each attack and only a small quantity of urine was passed. On one occasion her medical attendants (Mr. Osborne and Mr. Sandford Arnott) noted a tumour in the right iliac region.

The patient was kept under observation for some time in the hospital. Slight attacks of pain were frequent, during which a tumour was felt in the right iliac region and a peristaltic storm around it. An exploration having been agreed to an incision was made through the right rectus. On introducing the finger a small tumour was felt in this region, moveable and so insignificant as to be readily lost when released. When brought to the surface it proved to be a small ring carcinoma, of the variety in which the [illegible] would result from tightly [illegible] The tumour and about [illegible] were removed and also some glands from the mesentery. The two cut ends of the bowel were then closed and a lateral ileo-colostomy was made. The after-course was quite uneventful and on the twenty-eighth day the patient left the hospital. The bowels were acting regularly and no attack of pain had occurred subsequently to the operation.

Remarks by Mr. MAKINS.—The notes of most of the above cases were made by the dresser, Mr. Dean. They do not call for much comment but it may be remarked that Case 1 was an instance of volvulus of the cæcum, a variety which in contradiction to the statements found in most of the text-books has been much more frequently met with at St. Thomas's Hospital than volvulus of the sigmoid flexure. In Case 3 the symptoms were remarkably typical of strangulation by a diverticulum. Thus there was a history of several less severe incomplete attacks and the characteristic moderate degree of strangulation due to the strangulating agent being furnished by a soft rounded cord. The presence of follicular inflammation in the diverticulum itself has already been remarked upon. Case 4 is of special clinical interest as illustrating the combination of signs of intestinal toxæmia and obstruction, two conditions often very difficult of differentiation. Case 5 again offers an excellent illustration of the comparatively subacute nature of the signs and changes when the strangulating band is furnished by an intestinal diverticulum. In Case 7 the main points of interest were the small size of the tumour and the fact that it was only readily palpable when peristalsis was abnormally vigorous; on the other hand, the remaining lumen of the bowel was as small as could be possibly compatible with the onward flow of the intestinal contents at all.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Hypertrophic Pulmonary Osteo-Arthropathy.

A MEETING of this society was held on Jan. 12th, Mr. ALFRED WILLETT, the President, being in the chair.

Dr. H. E. SYMES-THOMPSON read a paper on Hypertrophic Pulmonary Osteo-Arthropathy. He said that the condition of certain bones and joints to which this name was now generally applied was not looked upon as a separate entity among bone and joint affections till 1889, when Bamberger demonstrated two cases of bronchiectasis with clubbing of the fingers and painful enlargement of the ends of certain long bones. I[illegible] and also four cases of [illegible] milar disturbances. M[illegible] pertrophic pulmonary osteo arthropathy for the affection and clearly differentiated it from acromegaly, to which it bore some resemblance. The term "hypertrophic pulmonary osteo-arthropathy" had been retained in this paper but the disease was called osteopathy for purposes of brevity. Hypertrophic pulmonary osteo-arthropathy was a chronic symmetrical disease of the bones, the joints, and the soft parts, affecting chiefly the distal segments of the extremities. The changes in the bones consisted chiefly in the deposition of friable new bone under the periosteum, in a sclerosis of the cancellous parts of the bones, and in the appearance of hard new bone in the diaphyses, encroaching on the medullary canal. In the joints involved an intermittent passive effusion was the most characteristic manifestation, but in certain cases the effusion was accompanied by evidence of inflammation. The joint cartilages were often the seat of erosions and in some cases there was vacuolation also. A progressive thickening of the soft parts round the joints usually took place but the thickening was never very great and it did not involve the skin. Clubbing of the fingers and toes of a special kind was nearly always present. There was no softening or suppuration in the bones or joints in osteopathy. Of the above changes those in the joints were the most evident clinically, while those in the bones quite overshadowed the joint changes in skiagraphs and in the post mortem room. The disease was much commoner in males than in females. Between 30 and 40 years was the commonest decade for osteopathy and the next most common period was between 20 and 30 years. Osteopathy was probably always secondary to some other disease and in the great majority of the cases the primary disease was a chronic suppuration in the thorax. It was caused occasionally by suppuration elsewhere but in such cases some disease of the lungs was generally present. Congenital heart disease was sometimes responsible for osteopathy and in a few instances syphilis was the only disease present. The same conditions which caused osteopathy probably led to the clubbing also. The above causes of osteopathy probably acted by producing poisonous bodies which circulated in the blood. The theoretical considerations on which this view was based might be summarised thus: toxic products, whether the result of normal metabolism or of an infective process, might be divided into two varieties—volatile and non-volatile. The volatile toxins were eliminated under healthy conditions by the lungs in the expired air. The non-volatile toxins were eliminated for the most part by the cells of the liver. If for any reason the eliminating function of one of these organs was interfered with, the toxins over the fate of which the lungs or the liver respectively presided would not be sufficiently eliminated and would accumulate in the blood. This gave an explanation of the almost constant association of pulmonary disease and osteo-arthropathy. If the liver was for any reason unable to carry on its detoxicating work the other organs, such as the spleen were capable of taking its place. If, on the other hand, anything interfered with the amount of respiratory surface available in the lungs the volatile toxins had no other way of escape and they therefore accumulated in the blood. If these conclusions were correct the presence of a toxic focus in the lungs was not essential for the production of osteopathy. What was essential was the co-existence of a toxic focus somewhere in the body with a condition of the lungs which interfered with normal respiratory interchange—e.g., a fibrosis, or even a chronic congestion only.

Dr. C. THEODORE WILLIAMS, after congratulating Dr. Symes-Thompson on his paper, said that he had not seen any large number of cases of hypertrophic pulmonary osteo-arthropathy. On the other hand, he had seen a very large number of cases of bronchiectasis but had very seldom seen hypertrophic pulmonary osteo-arthropathy follow that disease. Dr. Symes-Thompson had shown that as the pulmonary discharge varied the condition of the bones also varied. It was, however, difficult to see how such variation could take place if there was an actual thickening of bones. Dr. Symes-Thompson had attributed the disease to a toxin and had also stated that the disease occurred in congenital heart disease; it was difficult to conceive what toxin could be produced in congenital heart disease which would give rise to osteo-arthropathy.

Dr. PERCY KIDD mentioned four cases which he had recently seen. In one there were tuberculosis of the sternum and but little affection of the lung. He thought that the important change in most cases was an arthritic change and not an osteo-arthritic. In one of his cases there had been marked pain and there was marked thickening around the joint. In one of the cases examined after death there was no change in the joint but marked thickening around the joint. He referred to a case in which there was hypertrophic pulmonary arthropathy but without any physical signs of disease of the lungs. Some time later signs of growth in the lung occurred and the patient died. The joint symptoms had then been in existence for two years. He was of opinion that the growth was not the cause of the osteopathy in this case. This patient had developed hair on the face and other male characteristics which suggested some altered metabolism. He quite agreed with Dr. Symes-Thompson that the disease was due to a toxin. In the earliest stage of the disease it rather closely resembled rheumatoid arthritis.

Dr. R. MAGUIRE said that the theory which regarded the lung as a "gland" was one which was too often neglected. Some of the acute attacks of dyspnœa which occurred without there being any signs of disease in the lung were attributable to some altered function in the "gland." He mentioned the case of a boy, aged 16 years, who suffered from bronchiectasis with a cavity at the base of the lung. The temperature was very irregular and this was probably due to absorption of toxic material. There was a considerable amount of fœtid sputum. Swelling of the tissues around the joints and effusion into the joints were present. Intravenous injections of formaldehyde were given, the temperature became more regular, and the joints less swollen, and at the same time the amount of sputum was also diminished. This result was the exact reverse of that obtained in the cases mentioned by Dr. Symes-Thompson for in them as the amount of expectoration increased the joint trouble began to improve. He was of opinion that the joint trouble was due to invasion by a micro-organism.

Mr. W. G. SPENCER said that he considered this affection rather one of the joints than of the bones, but that it was difficult to draw a sharp line between the early stages of this disease and chronic pyæmia. He did not think that the toxic theory could alone explain the condition but that venous congestion might play a very important part in its production. He referred to the joint affection which occurred in "mother-of-pearl" workers who were for the most part young girls. This disease appeared to be due to the irritation of the lung by dust. He was of opinion that the question of the cause of the disease was a more complicated one than could be explained by the presence of a toxin only but that venous congestion played an important part.

Dr. G. NEWTON PITT referred to the fact that in the advanced cases there might be thickening of the bones, clubbing of the fingers, and affection of joints, but that in the earlier cases only one of these might be present and this might render the diagnosis difficult. He suggested that it was important to examine the medulla of other than the long bones so as to show if any inflammatory conditions occurred in them also.

Dr. S. RUSSELL WELLS suggested that in the human body, as in the laboratory, organisms grew best on certain media and thus the disease tended to affect certain tissues. As the disease affected cartilage and fibrous tissue in the lung, so in the same way it affected those parts of the body in which fibrous tissue and cartilage occurred—viz., the joints.

Dr. SYMES-THOMPSON replied.

MEDICAL SOCIETY OF LONDON.

The Use of Serum and Other Inoculations in Pyogenic Infections.

A MEETING of this society was held on Jan. 11th, Dr. F. DE HAVILLAND HALL, the President, being in the chair.

Mr. W. G. SPENCER opened a discussion on the Use of Serum and Other Inoculations in Pyogenic Infections by reading a paper on the Use of Antistreptococcic Serum Streptococcus infection presented itself clinically under many forms—e.g., erysipelas, septic inoculation of the extremities, septic pharyngitis, scarlet fever, puerperal fever, endocarditis, pneumonia, or pleurisy. Any one of these forms might take such a virulent course that the indirect methods of treatment available to the physician proved inadequate. A generalised streptococcal infection was diagnosed by finding streptococci in the blood and no definite proof of the value of antistreptococcic serum could be deduced from any case in which the streptococcus has not been found in the blood beforehand The blood should certainly be examined repeatedly in all cases in which the antistreptococcic serum was being administered, but difficulties and delays in carrying out bacteriological examinations were often inevitable and time was an essential factor in the commencement of the treatment. However, apart from the examination of the blood, clinical observation went far to establish streptococcal infection in many of its varieties. The difficulties of producing a satisfactory antistreptococcic serum were then referred to. It was very probable that many reported cases of failure might have been due to the serum never having been standardised or to its having subsequently become inert. The essential requirements for the successful use of the serum were as follows: (1) evidences of a general infection by streptococci; (2) a standard antitoxin; (3) early administration after onset of the fever; (4) subcutaneous injection, and, perhaps, in very severe cases, intravenous injection; the administration by the mouth or rectum might be rejected and summarily dismissed; and (5) the administration of full doses every three or four hours until relief. Failure to comply with these requirements might explain many possible sources of failure Reference was then made to the clinical varieties of streptococcus infection. 1. In acute septic pharyngitis the best results had followed the administration of streptococcal antitoxin. 2. In cutaneous erysipelas, especially of the face and head, the indication for the serum treatment in this class of case was limited. 3. In cellulo-cutaneous erysipelas there was for the most part local suppuration due very often to a mixed infection with staphylococci; hence the issue was confused. 4. Scarlet fever Dr. Klein had for many years connected with a variety of streptococcus and this view of the pathology of the disease appeared to be generally accepted. Certain cases of malignant scarlet fever had been successfully treated by the serum 5. In puerperal fever they reached the most important section of the subject. The chief cause of fatal puerperal fever mainly consisted of streptococcal infection. It was, however, erroneous to infer that puerperal fever was invariably streptococcal in origin. Staphylococci and gonococci might cause the infection, even the diphtheria and colon bacillus had been found in the lochia. 6. Cases of endocarditis and pericarditis were either secondary to some local lesion or, when arising primarily, were diagnosed by finding streptococci in the blood. In primary cases it was essential to find streptococci in the blood beforehand and to note their disappearance after the administration. 7. In cases of septic pneumonia and empyema the serum had been administered but with very doubtful benefit. In conclusion, Mr. Spencer expressed the belief that there were abundant reasons for the proper use of antistreptococcic serum. There should be available for the practitioner an abundant supply of active standardised serum of the special kind required for use at the shortest notice.

Dr. A E. **WRIGHT** communicated a paper on Inoculation in cases of Staphylococcal Infection. He remarked that he would confine his attention to that kind of immunisation which was developed within the patient, such as could be accomplished in chronic or recurrent suppurative disorders, acne, boils, sycosis, and other suppurative conditions in the skin, and chronic generalised pyogenic conditions. Reference was made to a man who infected his finger, the infection from which spread up the arm and became generalised and chronic for ten years, the general staphylococcal infection taking the form of repeated crops of boils and suppurative lesions in various parts. Dr. Wright had administered staphylococcal vaccine prepared from dead cultures and the patient had rapidly recovered. Five other cases were treated with like success.[1] 15 more cases (making a total of 21) of chronic recurrent suppurative conditions had been successfully treated in this way. Cases did best if treated by the vaccine derived from their own staphylococcus. Cases required watching and the treatment adapted from day to day. The phagocytic reaction might vary considerably and in a negative phase go down to 0·5 of normal. Similarly the serum of immunised animals might vary and that was why the sera on the market were untrustworthy.

Sir **FELIX SEMON**, referring to the treatment of acute intoxications—Ludwig's angina, for instance—remarked that they were not necessarily of streptococcal origin, they might be due to any of the pyogenic group of organisms. The treatment to be of any use must be extremely prompt. The sera on the market were better than nothing.

Dr. E W. **GOODALL** thought they had not advanced very much in the last four years in their knowledge of the subject. In regard to scarlet fever Marmorek's serum had entirely failed. He did not agree that the streptococcus agglomeratus was the organism of scarlet fever, though no doubt the pyogenic complications might be due to streptococci, and reference was made to a case of severe angina in which recovery very rapidly took place under the serum treatment.

Dr. **CYRIL OGLE** had collected records of 110 cases treated by antistreptococcic serum. The results of his analysis showed some very hopeful results.

Dr. W. J. **GOW** referred to puerperal fever and expressed the belief that no real good had been accomplished in puerperal cases. The uncertainty of the serum on the market was a grave objection. Results would necessarily be fallacious, for many puerperal women incurred considerable temporary elevations of temperature which subsided spontaneously or under simple local measures.

Dr. F. J. **POYNTON** remarked that no one knew the nature of the several pyogenic cocci. The difficulty of preparing the sera was very great. The sera on the market were antibactericidal, which property was very easily and rapidly lost. Evil results arising from their use had been recorded, such as multiple arthritis and enlargement of the spleen.

The **PRESIDENT** thought that in desperate cases the use of these sera was justified. He had recently treated five cases; two were severe cases of erysipelas, one was a case of malignant endocarditis, one of Ludwig's angina, and one of septic pneumonia. Early administration was very important. Other precautions should not be neglected. Several extraordinary recoveries had been recorded when the sera had been administered by the mouth or the rectum.

Mr. **SPENCER** and Dr. **WRIGHT** replied.

CLINICAL SOCIETY OF LONDON.

Pneumococcal Peritonitis.

A MEETING of this society was held on Jan. 8th, Dr. **FREDERICK TAYLOR**, the President, being in the chair.

Sir **DYCE DUCKWORTH** and Professor **HOWARD MARSH** communicated a paper on a case of Pneumococcal Peritonitis. The patient, a woman, aged 27 years, was seized with headache, generalised pains, and a rigor on Feb. 26th, 1903. The temperature was found to be 104·2° F. on the following day and symptoms of general peritonitis followed. Widal's reaction was negative and a large polynuclear leucocytosis was present. On March 2nd Professor Marsh and Mr. A. A. Bowlby saw the case and a diagnosis of typhlitis with some general peritonitis was made. Professor Marsh operated and signs of inflammation were seen in the peritoneum and the large intestine. The appendix was found to be constricted at the base, dilated, and full of mucus above; it was ligatured and removed. There was some thin, turbid, and dark-coloured fluid in the peritoneal cavity but no adhesions were found nor was there any evidence of the perforation of a viscus. A culture of the fluid showed pure specimens of the pneumococcus, the presence of which was confirmed by an inoculation test. Three days later hiccough and abdominal pain supervened and ten cubic centimetres of No. 1 antipneumococcic serum were injected. On March 6th the injection was repeated. Signs of fluid in the left pleura appeared and on the 20th pus was found on exploration. Resection of part of the ninth rib was performed on the next day, when 12 ounces of sour-smelling pus were evacuated. The further progress of the case, though slow, was uneventful. The sudden onset and the rapid and grave development of the peritonitis closely corresponded with that which is observed in pneumococcal inflammations in the joints and elsewhere.

The **PRESIDENT** also communicated a case of Pneumococcal Peritonitis. The patient was a girl, aged eight years, who was admitted under his care into Guy's Hospital on Nov. 19th, 1903. On the 10th abdominal pain set in, followed by a rigor, and two days later signs of pneumonia developed. On admission the abdomen was distended and tender, moving very little on respiration, while physical signs of pulmonary consolidation at both bases were present. Some herpetic vesicles were seen at the base of the nose. Mr. R Clement Lucas performed laparotomy and a quantity of odourless pus together with masses of lymph was removed. The cavity was irrigated with hot saline solution and drained. The pneumonia on the right side cleared up but on the left side physical signs of empyema manifested themselves and on the 27th six ounces of pus were withdrawn resection of a portion of rib being performed four days later when more pus was evacuated. Cultivations made by Dr. J. W. H. Eyre from the peritoneal pus gave a pure growth of the pneumococcus; those taken from a second collection in the left iliac fossa which was incised on Dec. 11th gave a growth of pneumococcus associated with the staphylococcus aureus. Cultivations from the pus aspirated from the chest were sterile but under the microscope showed badly staining diplococci and empty capsules, characteristic of a pneumococcal empyema. The child was making good progress. The President discussed the question of the seat of primary infection which he thought was shown by the sequence of events to be the lung; the peritonitis and empyema he considered were secondary.

Mr. **STANLEY BOYD** referred to the case of a woman, aged 26 years, upon whom he had operated for symptoms of peritonitis, three pints of odourless pus being evacuated from which pure cultures of the pneumococcus were obtained. The abdomen was distended in a peculiar fashion and moved with surprising ease. No information was forthcoming at the time of operation as to the primary origin of the disease but the possibility of infection through the pelvic organs might be considered.

Dr. J. H. **BRYANT** alluded to three cases of pneumococcal peritonitis which he had published in 1901 in which the primary point of infection was the peritoneum. He considered that an alimentary origin was not at all improbable, especially as the pneumococcus might be found in the throats of healthy individuals. He called attention to the fact that abdominal pain was frequently complained of in pneumococcal pneumonia and he thought that the adhesions sometimes found post mortem between the lung and the diaphragm might account for this. Pneumococcal peritonitis was rare; of 162 cases of pneumococcal infection reported by Dr. Netter of Paris, in only two had the peritoneum become infected.

Dr. J **FAWCETT** stated that in 182 fatal cases of lobar pneumonia which had occurred in Guy's Hospital during the last five years and in which necropsies had been made five only showed any evidence of infection of the peritoneum and this was very slight. The conclusion to be derived was that in pneumococcal peritonitis the infection was generally a primary infection of the peritoneum or part of a general septicæmia.

---

[1] THE LANCET, March 29th, 1902, p. 874.

Dr. W. LANGDON BROWN referred to a case of pneumococcal empyema in a girl, ten years of age, in whom signs of fluid appeared in the abdomen and right knee-joint. The abdomen was not opened as the condition cleared up He considered that this was probably a case of pneumococcal peritonitis in which recovery ensued without surgical interference.

Mr. C. H. GOLDING-BIRD said that although a tuberculous appendicitis was known, yet pneumococcal appendicitis was not as yet recognised. He thought that there were many points in Professor Marsh's case which might justify the latter description.

Dr. EYRE felt sure that if bacteriological examinations were made more frequently than they were the pneumococcus would be more often found. He called attention to one curious property possessed by the pus from these cases—namely, its tendency to auto-sedimentation, the upper layers soon becoming clear. He thought that such a simple test might be found of assistance at the time of operation. He also pleaded for the importance of performing animal inoculation experiments as a confirmatory test for the presence of the organism. Staining tests were fallacious.

Dr. HERBERT S FRENCH read notes of a case under the care of Dr. G. Newton Pitt in which he had performed the necropsy. Acute peritonitis with consolidation of the base of one lung was found. He thought that the cases might be divided into groups, one where the infection was directly into the peritoneal cavity and another in which the organisms entered the blood and so disseminated themselves.

Sir DYCE DUCKWORTH, in reply, said that he thought that pneumococcal peritonitis might exist in varying degrees of virulence. The improvement in his case after the use of serum was certainly *post*, if not *propter*, *hoc.*

Professor MARSH replied that he was unable to state whether the case was one of primary appendicitis. He thought that to the list of conditions which might imitate appendicitis pneumococcal peritonitis must be added.

The PRESIDENT, in reply, said that the presence of an extraperitoneal abscess containing pneumococci in association with another organism was an interesting feature in his case.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Treatment of Tuberculosis by Beraneck's Tuberculin.—Successful Operation for Typhoid Perforation.—Pylorectomy and Gastro-jejunostomy performed Five Years after Operation for Perforating Gastric Ulcer.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 8th, Mr. C. RICHARDSON, the President, being in the chair.

Dr. A. CHRISTY WILSON (Doncaster) read a paper on the Treatment of Tuberculosis by Beraneck's Tuberculin and said that he believed that the view was steadily increasing among those who had seen most of the results of the open-air treatment of consumption that the cures were not so numerous as was at first anticipated. He became acquainted with Beraneck's tuberculin as a result of several visits to this observer's laboratory in Neuchâtel. It was claimed that this tuberculin was innocuous and convenient in the treatment of tuberculosis. It was obtained by a mixture of basitoxins and acidophile toxins of the tubercle bacillus. It was less toxic than Koch's tuberculin. The patient was injected daily, the initial dose being about 0 002 gramme. The presence of hæmoptysis was no contra indication. The larynx had been painted with the pure tuberculin for several weeks with no inconvenience. Improvement had been noted in 60 out of 90 cases of phthisis. Dr. Wilson, in conclusion, gave details of some illustrative cases.—Dr. E. F. TREVELYAN drew attention to the fact that Beraneck's tuberculin appeared to be prepared on much the same lines as Koch's old tuberculin and tuberculin R and he doubted whether an active immunisation by toxins was likely to provide a really efficient treatment of tuberculosis. After some actual experience of sanatorium treatment he was quite prepared to admit that something more was wanted, no doubt in the shape of a bacteriological treatment, especially in cases with persistent pyrexia. If Beraneck's tuberculin was as harmless as Dr. Wilson maintained it was only right to try it.—Dr. T. CHURTON also took part in the discussion and Dr. WILSON replied.

Dr. A. G. BARRS and Mr. WALTER THOMPSON described a case of Successful Operation for Typhoid Perforation occurring in a young woman. Dr. Barrs gave a clinical outline of the case and emphasised the importance of early diagnosis. The operation was performed on Oct. 5th at 11 P.M., two hours after the occurrence of perforation. The patient was suffering severely from shock at the time. She was therefore infused with saline solution and five minims of strychnine were injected subcutaneously. Under ether an incision was made four inches long in the right linea semilunaris On opening the abdomen some four or five ounces of turbid fluid were found. There was no fæcal odour or escape of fæces, the intestines being small and empty. A small, cleanly punched out perforation was found about four inches from the ileo cæcal valve. It was of about the size of a filiform bougie and was so small that it was missed at the first examination. The whole ulcer and perforation were inverted with a single continuous suture. Two other ulcers which had roughened the peritoneum were treated in the same manner. The abdomen was cleaned and drained with gauze. The greater part of the wound was closed. For the next four days it was impossible to say whether the patient was suffering from general peritonitis or not. The wound suppurated and healed slowly. She was now well.—Dr. CHADWICK, Dr. CHURTON, Mr. H. LITTLEWOOD, Mr. B. G. A. MOYNIHAN, and the PRESIDENT took part in the discussion, and Dr BARRS and Mr. THOMPSON replied.

Dr. CHRISTY WILSON showed a case of Pylorectomy and Gastro jejunostomy performed five years after operation for perforating gastric ulcer. On May 3rd, 1901, he read before a meeting of the society notes of four cases of perforation of the stomach and duodenum. The patients, all men, were treated in the Doncaster Infirmary and, he believed, were cured not only of the perforation but of the ulcers and indigestion. Two out of the four had had recurrence in the site of the original ulcer. One recovered after three weeks of rectal feeding followed by dieting and one came back five years after his first operation (May 14, 1903). Pale, emaciated, and scarcely able to walk, he relapsed six months after his perforation. One and a half hours after every meal he had severe pain and usually vomited. Two weeks of rectal feeding and dieting doing no good the abdomen was opened by cutting through the cicatrix of the old incision. Dense adhesions surrounded the pyloric end of the stomach and the duodenum. They were very vascular and presented many large veins which were very friable so that it was somewhat difficult to clear the stomach and duodenum. The pylorus was thickened and indurated, so the duodenum was divided an inch and the stomach one and a half inches from the pylorus. As they would not approximate both were closed and a posterior gastro-jejunostomy was performed. The patient's recovery was rather slow but three months after admission he returned to his work and had continued perfectly well ever since. Examination of the specimen showed that the pylorus was occupied by a large ragged ulcer with an indurated base, but fortunately for the patient it was not malignant.

The following cases and specimens were exhibited:—

Dr. C. OLDFIELD: (1) A specimen of Hydatidiform Mole; and (2) a case of Pyosalpinx.

Dr. CRAWFORD WATSON (Halifax): A case of Splenic Enlargement.

Mr. LITTLEWOOD: (1) Suppurating Fibroid removed by Abdominal Hysterectomy; (2) a Portion of Catheter removed from the Male Bladder; and (3) two specimens of Ovarian Cysts associated with Pyosalpinx.

Dr. CHURTON: Three cases of Recovery from Tuberculous Meningitis.

Dr. J. B. HELLIER: Specimens of Tubal and Ovarian Disease.

Dr. J. GORDON SHARP: A case of Periodic Tonic Spasm of the Muscles of the Right Upper Extremity following Injury to the Left Motor Area.

Mr. MOYNIHAN: A series of specimens from cases Enterectomy, Colectomy, and Proctectomy.

Dr. CHADWICK. A case of Aneurysm.

Dr. A. L. WHITEHEAD: A case of Empyema of the

Frontal Sinus, right Sphenoidal Sinus, both Antra of Highmore, and of the Ethmoidal Cells on both sides.

Mr. G. CONSTABLE HAYES: Skiagram and specimen of a Piece of Steel removed from the Eye by Mr. H. Secker Walker with the Electro-magnet.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

On the Treatment of Various Forms of Cutaneous Disease by the X Rays and Light.

THE fourth meeting of this society was held on Jan. 8th, Professor JOHN CHIENE, the President, being in the chair.

Dr. W. ALLAN JAMIESON read a paper on the Treatment of Various Forms of Cutaneous Disease by the X Rays and Light. He said that the epidermis when structurally intact had hitherto offered such an impenetrable bulwark and so successfully protected the underlying structures that agents designed to exert action on tissue elements only very little beneath the surface had been found uncertain and inefficient. No doubt this statement, as Unna had shown, required modification when the epidermis had become unsound and therefore porous. A certain and sometimes an undesirable amount of absorption was then possible but this very unsoundness restricted their efforts as harm might easily be wrought. Hitherto their means had either been direct caustics or those which occasioned irritation in the first instance, as iodine. Quite recently, however, the introduction of the x rays, of the Finsen light under favourable conditions, of radium, and of high-frequency currents had assuredly given them sources of energy which could influence the various tissue elements in and beneath the epidermis. Dr. Jamieson limited himself to a consideration of the results obtained in the Edinburgh Royal Infirmary since the employment of the x ray and light treatment was introduced. He referred to the improvement in the old spring contact breaker by its replacement by a mercury motor interrupter and the beneficial results in treatment thus effected. Constant supervision of the cases under treatment was necessary so as to observe the earliest signs of reaction and thus to cease the exposures before the limit had been materially passed. There were instances where the reaction did not show itself until days, or occasionally even weeks, after the last exposure, but when such appeared so remotely it was seldom severe. Another point which had been closely considered was the protection by lead masks of parts other than those involved in the disease. When affected areas encroached on bearded portions the shedding of hair could not be wholly avoided, but this was a minor ailment, particularly as the hair usually after a time returned. The distance from the tube had also occasioned considerable thought, as while the nearer the more intense the effect there was also a greater risk of burning. Hence a mean of from four to six inches had been adopted. The duration had been on an average five minutes to each part exposed. Working with a comparatively high ampèrage and low voltage since accumulators were used exposures were made with a cold anti-cathode. While not in any way courting reaction it had been found that a moderate degree was not harmful. Indeed, it was a good test that the rays were acting on the tissues, but since no one could say how far in any given case such reaction might go further exposures were stopped on its appearance. Burns of any severity had occurred almost exclusively in cases of lupus or in favus or sycosis of an intractable kind where the rays were of little or no account. No scars from burns had been met with in cases of rodent ulcer or in the two cases of mycosis fungoides. Sometimes the plan suggested by Dr. Norman Walker of painting with pure carbolic acid where the disappearance of the lesion was slow had been followed by improvement. This had chiefly been employed in lupus vulgaris where great variations in the sensitiveness to the rays was found. A small number of cases, however, reacted to but one or very few exposures and the interval had in them to be prolonged. The tubes often became somewhat rapidly "hard" and in his experience less active. He had not found "soft" tubes, those having a sparking distance of over three inches, particularly apt to burn, while they were certainly more efficient in curing the disease. He had found that weather conditions materially affected the rays, that on cold raw days reactions more readily occurred and this was what might have been expected; but while cold was one it was not the sole climatic condition which favoured reaction. During the last 18 months 133 cases of lupus vulgaris had been treated and the greater proportion of these by exposures to the x rays. Some, however, had been treated exclusively, whilst a large number had been partially treated, by the Finsen light. Of favus 30 cases, of rodent ulcer 21, and of sycosis 12 had been treated and in addition two cases of mycosis fungoides. Unfortunately, the results could not be stated statistically as nearly all the patients treated were out-patients. Some discontinued attendance or the exposures were interrupted for various reasons. It might be said generally, however, that [illegible] who persevered had [illegible] benefited. 1. As re[illegible] largely, formerly in all forms of treatment, while the centre might be cured, the margins of the area were apt to remain the seats of active disease which ever tended to encroach on healthy skin. In very many examples the effect of x-ray treatment was to check the progress at the margins which scarred over but small nodules might persist in the centre; yet this also greatly improved, though, if extensively involved, the interior of the nostrils might need the employment of scraping or other topical medication; in not a few the crusting, so suspicious a feature, might completely dry up under the x rays alone. Undoubtedly, the soil in lupus had to be reckoned with. When the skin was soft, pale, and tender and the patient exhibited very markedly the signs of the strumous diathesis, such patients were somewhat prone to react readily and not always went on as satisfactorily as could be wished. This, however, was no valid reason for not employing the rays, as in many most [illegible] excellent results were obtained. [illegible] not be quite sure of ultimate [illegible] be immensely reduced and so brought within manageable limits. Other and older methods were quite compatible with the use of the rays and could be employed with advantage as auxiliaries. An important question had been raised as regards metastases. In the treatment of a case of lupus by the x rays tuberculous peritonitis and abscesses had developed in other parts of the body, but this was a solitary example and it was most unlikely that the action of the rays was to set the bacilli free in the circulation after the manner ascribed to tuberculin. Dr. Jamieson had found that the modification of the Finsen light provided by the Marshall and Woods lamp was most applicable to small patches of lupus where firm pressure could be exerted owing to their situation over bony structures or for residual nodules similarly placed after x-ray treatment. He related one case treated exclusively and most successfully by the Finsen light and others nearly as successful had resulted. This method had the advantage of not causing burns but was much more restricted in its applicability and the progress was slower. The application of adrenalin to the lesions shortly before exposure to the lamp was abandoned as the exaltation in effect was not at all commensurate with the expense. 2. Rodent ulcer. The curative effects of the x rays on this disease were now universally conceded. Perhaps the best results of their unaided use were obtained in cases of fungating rodent ulcer of the face. When progress was watched the margin was seen to recede and with the absorption of the new growth healthy epithelium advanced from without inwards. The more completely the rodent ulcer was limited to the skin and subcutaneous tissue the more brilliant was the success, but even when periosteum and bone were implicated a cure might follow. In other forms of cancer, however, the effects had not always been so good and in one advanced case fresh masses of cancerous growth sprouted up even when the rays were being actively employed. The rays found their special field of applicability in situations such as the nose, where excision was likely to occasion great disfigurement. In order to shorten the time required for the absorption of patches of rodent ulcer it was desirable to get rid of as much of the new growth as possible by scraping, together with [illegible] to small areas at a time. A[illegible] Jamieson could not speak [illegible] might recur even after prolonged exposures and apparent cure was shown in the case of a man, aged 58 years, who had been treated energetically two years previously for extensive superficial rodent ulcer of the cheek but who now exhibited a marginal extension in the shape of a deep groove all round the still healthy cicatrix. Some held that the x rays had less control over recurrence after previous use. 3. Sycosis. Only intractable cases had been treated. Some of these stood the application with merely the production of a sensation of heat, while in others swelling, redness, and pain rapidly followed. In all after a longer or shorter period the hairs fell out while the pustules became fewer and fewer. Yet unless the part could be rendered absolutely bald and a smooth, white, scar-like surface left the disease might recur. In such cases the fine returning hairs on being extracted were seen to have a minute amount of pus at the root. 4. Favus. With loosening and pulling out of the hair the disease died out, a polished, hairless surface remaining. In some cases exposures amounting to an hour caused separation of the hairs, in others a much longer period was required. Cases of favus did not usually react unduly. 5. Mycosis fungoides. In this rare disorder the rays had proved to be the sole means of arresting an otherwise hopeless disease. Dr. Jamieson had treated a patient more than a year ago and at present she remained well, in so far that all the parts of the body then exposed to the rays continued to be free from recurrence, yet one or two patches and two small tumours had developed in situations which were not submitted to the rays. Another case in the erythrodermic or premycotic stage had so greatly improved as to be almost well. (The patient was exhibited.) As regards the mode of action of the x rays, it was widely accepted that they exerted no directly lethal effect on microbes and this was supported by what occurred in sycosis. Though the rays had the power of causing the separation of the hair from its papilla and of inhibiting its growth and renewal at least for a time they only killed the staphylococci by removing the pabulum furnished by the hair and its sheaths *in situ* and by emptying the follicular tube much in the same way as an alveolar abscess ended when the offending tooth was extracted. In proof of this it had been shown that in sycosis the vitality of the staphylococci was not wholly destroyed since pustules reappeared in places coincidently with the re-growth of the young hair. In favus epilation had been for long the favourite method of cure and the rays merely did this more thoroughly and naturally but did not of themselves put an end to the achorion. The apparent bactericidal action in lupus could be best explained by their promoting phagocytosis. The bacilli were few in number and scattered throughout the nodules and were thus readily dealt with when the polynuclear leucocytes were increased in number and activity. In mycosis fungoides and rodent ulcer non-microbic diseases were met with, and the notable effect of the rays in these diseases seemed purely owing to a power which they possessed of recalling aberrant cells to obedience to trophic nerve control. Dr. Jamieson exhibited many patients to show the results of treatment in various skin diseases.

Dr. **WALKER** said that time was a great consideration and the period available for treatment had in each case to be determined carefully. The extent of the disease and the circumstances of the patient might allow of one or two prolonged exposures with a soft tube. Considerable destruction might be a result in such cases and though the healing was slow less time, on the whole, was lost. Telangiectases might occur but were easily cured by electro-puncture. He narrated cases to illustrate the good effects of exposures made at considerable intervals. In cases of rodent ulcer it did not seem to matter whether hard or soft tubes were employed but the difficulty was in knowing when to stop. Ulcerated cases did best and the resulting scar was excellent. He referred to the cosmetic effect of the x rays as contrasted with surgical procedure in cases where the cartilage had been attacked. In cases of hypertrichosis they would naturally have expected that the condition would be benefited but in Dr. Walker's experience the results had not been sufficiently certain to lead him to recommend the treatment. Where the hairs were diseased and where their removal was desired as part of the treatment this method was applicable. In favus the effects were most satisfactory but not so in ringworm for the simple reason that the hairs broke off. In sycosis experience had taught that removal of the hairs was not sufficient and the effects of treatment of this disease by the x rays confirmed the view that such rays were not germicidal. Dr. Walker referred to the inapplicability of the rays in the treatment of psoriasis and to their excellent effects in cases of widespread warty growths. Dr. Walker thought that as regards methods most depended on the lamp and that information gained from the operator's own apparatus was the most important of all. Too much stress could not be laid on the importance of protection. Dr. R. B. Wild of Manchester had very recently referred to the possibility of phthisis being set up by the treatment, death from phthisis having occurred in two out of his 80 cases. Dr. Walker agreed with him in thinking that there was no connexion between this result and the treatment. Dr. Wild gave the percentage of satisfactory results in the case of the Finsen lamp as 75, in x-ray treatment 74, and with the Lortet-Genoud lamp as 24. The results obtained in the Royal Infirmary, Edinburgh, were not dissimilar. Dr. Walker was satisfied that the x rays were at least twice as useful as the London Hospital lamp. Dr. Walker concluded by giving a warning against the indiscriminate use of such treatment and demonstrated many patients.

Dr. **DAWSON F. D. TURNER** remarked that metastasis was unusually common in scirrhus of the breast treated by the x rays. As only those rays which were absorbed could be of benefit he preferred soft tubes for superficial cases. For the proper treatment of disease by electrical methods some knowledge of physics was essential. The increase in the amount of unqualified electrical practice by so called institutes and by tradesmen was greatly to be deplored. Practitioners should recommend their patients to medical men who had had an electrical training. Dr. Turner exhibited the following:—1. A case of Scirrhus Erythema following removal of the breast; 46 exposures of four minutes each sufficed to remove it entirely. 2. A case of Fibro sarcoma of the Frontal Bone. It was so large that the right eye was almost entirely occluded. After only 11 exposures of four minutes each the swelling had greatly diminished and the patient could see easily with the right eye. 3. A case of Lupus under treatment by radium. 4. A Recurrent Scirrhus in which after 26 exposures the nodular and glandular swellings had disappeared. 5. A case of Recurrent Sarcoma[1] which had so improved after 48 exposures that the man had returned to his work.

Dr. **H. E. FRASER** said that the more abnormal the tissue the greater was the effect produced by the x rays. He thought that soft tubes were more liable to produce irritation. The erythema which resulted from treatment might not come on until the treatment had been stopped and the same occurred with sloughing. In one case of rodent ulcer an exposure of 25 minutes was accidentally given. A large slough formed but the result was most satisfactory and no recurrence had taken place a year later. The proliferating diseases as lupus and rodent ulcer seemed most easily and beneficially affected. The analgesic effects of this treatment were often great even though no benefit to the disease, as in a case of sarcoma of the ribs, resulted.

Mr. **D. M. GREIG** and Dr. **GARDINER** also took part in the discussion.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Jan. 8th, Dr. J. Groves, the President, being in the chair.—Dr. J. Spottiswoode Cameron, medical officer of health of Leeds, read a paper on the Sophistication of Foods. By this term he understood not only the addition or substitution for the genuine article of another having a plausible resemblance thereto and the partial removal of some valuable constituent, but also the addition without the knowledge of the purchaser of some foreign matter producing or preventing chemical changes in the food, unless its presence were essential and implied in the description. Thus a ham would not be a ham without salt and tarry matters and the use of salt alone was understood in the case of salt pork, beef, and fish. But in all these the undeclared addition of borax was a sophistication and if the consumer's health suffered he was wronged and entitled to redress, whereas if the presence and percentage of the boric acid were declared no one was to blame. Most persons preferred their coffee with a little chicory but the addition or substitution of 90 per cent. was clearly a fraud though legalised by Section 8 of the Act of 1875. As regards the addition of margarine to butter, the Act of 1899 appeared to be strict enough, but there being no standard of butter and the soluble fatty acids calculated as butyric acid varying from 4 5 to 7 per cent. nearly a fourth of its weight of margarine might be added with impunity. Milk was very largely diluted, for the effect of fixing a standard had been its acceptance not only by the trade but by magistrates as a normal, not as a minimum, and the very general practice of watering rich milks down to it. He hoped that the standard percentage of fat would be raised to 3·25, which several companies found no difficulty in obtaining. Two of the most "burning questions" in connexion with adulteration were those of preservatives and of warranties The result of fixing standards or permissible maxima of preservatives had been similar to that in the converse case of the minimum of fat in milk additions not greatly exceeding the maximum allowed being looked on as venial With the recent improvements in sterilising and preserving foods by heat or cold, by sugar, and the like, Dr Cameron saw no need for the use of chemicals which, if not poisonous, were at least of doubtful wholesomeness Formic aldehyde ought to be prohibited and the use of boric acid should be limited and discouraged The addition of copper salts for "greening" peas and other vegetables should be made illegal The recommendations of the committee on preservatives appointed by the Local Government Board were reasonable and he regretted that they had not long since received legal sanction The law with respect to warranties was in an unsatisfactory state The Margarine Act of 1887 had introduced the mention of invoices and as one result in several instances an invoice handed in had been held to exonerate the retailer, though when proceedings were taken against the wholesale dealer who had given it, it was declared to have nothing of the nature of a warranty and the summons against him had been dismissed Section 20 of the Act of 1899 dealt with the "use of warranty or invoice as defence and proceedings against the warrantor" but in Subsection 6, stating the penalty for giving false warranties, there was no mention of invoices —Mr C Cassal, F I C, said that a sample of butter was pronounced by himself and the chemist of the Board of Agriculture to contain 17 per cent. of foreign fats whereas it was found to have been made from the milk of two cows—one normal the other diseased and yielding a butter containing as usually estimated, about 30 per cent of fats other than those of milk, together with pus cells, shreds of tissues, coagula and bacteria of all kinds Such butter was a fraud, for it mattered not to the consumer whence the foreign matter was derived —Mr D L Thomas, medical officer of health of Stepney, said that he had to prosecute more than one s than 2 per cent of fat and on ich gave but 1½ per cent he found lent by one retailer to the other for the purpose of defence —Dr E F Willoughby remarked that all discussion and evidence in the courts and elsewhere turned on the question of the possible injury to health through the ingestion of single large doses, or the habitual use of small doses, of the preservative but in his opinion the question of the possible presence of ptomaines in the partially preserved milk was a matter of greater importance —The President, Mr J Tubb Thomas, and many others also took part in the discussion

---

[1] THE LANCET, Jan. 2nd, 1904, p 23.

LIVERPOOL MEDICAL INSTITUTION —A meeting of this institution was held on Jan 7th, Mr Rushton Parker the President, being in the chair —Dr A S I Grunbaum showed an experiment to demonstrate the hæmolytic action of Radium Rays on Red Blood Corpuscles —Dr R Stenhouse Williams exhibited and described a new ethyl chloride inhaler When the anæsthetic was administered by his method the patient was under its influence in 50 seconds, the anæsthesia was maintained with ether He had found it very useful in alcoholic subjects —Mr F W Bailey had noticed that patients frequently came out of the ethyl chloride anæsthesia before ether anæsthesia was induced —Sir William M Banks and the President also spoke —Mr R C Dun read notes of a case of Congenital Hydronephrosis due to stricture of the ureter at its junction with the renal pelvis The chief point of interest lay in the fact that the abdominal tumour was principally on the left side and was not palpable in the right loin The diagnosis of left hydronephrosis was made On performing nephrectomy through an incision on the left side a normal left kidney and ureter were exposed The tumour which proved to be a hydronephrosis of the right kidney, lay in front of the left kidney and was readily removed Recovery was uneventful A congenital displacement of the right kidney either to the middle line or into the loin of the opposite side probably explained the abnormal position of the hydronephrosis —Dr W Blair Bell and the President commented upon the case —Mr C Thurstan Holland read a note on the X Ray Diagnosis of Kidney Stones he laid special stress on the necessity, in making a negative diagnosis, of taking the x ray whilst the breath was held, also the importance of obtaining a plate showing the differentiation of the shadows of the soft structures lying between the iliac crest and the lower ribs The note was illustrated by a series of lantern slides showing stones *in situ* and also the type of negative to be aimed at —Dr W Carter, Dr Charles J Macalister, and Dr W Alexander spoke, and Mr Holland replied —Dr A Cassels Brown exhibited an old notebook containing notes on Dr John Rutherford's clinical medical lectures delivered in Edinburgh 1749 and read a paper on the subject After giving an account of Edinburgh the medical school, and Dr Rutherford, he referred to the total absence at that time of anything like scientific observation in medicine, but pointed out that the rate of mortality in Dr Rutherford's wards was in the existing circumstances not at all a discreditable one Dr Cassels Brown gave details of the treatment adopted in cases of anæmia rheumatism, ague, phthisis, syphilis, cardiac disease and hydrophobia, and in conclusion remarked that while the medical profession had advanced scientifically to an enormous extent, it had not advanced equally in other directions He suggested that more attention should be given to the teaching of practical therapeutics and advocated a modified return to the culture of the old time physician —The President, Sir William Banks, Dr Grunbaum, and Dr J R Logan spoke, and Dr Cassels Brown replied

ROCHDALE AND DISTRICT MEDICAL SOCIETY —At a meeting of this society held on Jan 7th Mr S T Lord read a paper on Functional Nerve Troubles Modern views of the nervous system recognised a conscious, a subconscious, and an unconscious mind An important function of the unconscious mind was inhibition In hysteria the inhibitory function was more or less in abeyance and hence a slight stimulus produced a fit In neurasthenia there were two factors, diminished resistance which was hereditary, and excessive strain Everyone was more or less susceptible to the influence of suggestion in fact, any so called voluntary action might be looked upon as the resultant of a complex series of suggestions How much more susceptible to this influence must those be whose nervous systems were weak or unstable Cases were related illustrating functional nerve trouble In all of them drugs had proved useless A girl with hysterical knee joint was cured when treatment had been given up A boy with a stiff and intensely tender elbow was perfectly well after being under chloroform and told that he was better Cases of hysterical vomiting were cured one by the threat of a thrashing, one by passes practised by a quack, and another by the suggestion of rectal feeding A boy subject to cataleptic fits had them averted by a box on the ear from a friend A neurotic mother had a son and twin daughters all subject to hysterical vomiting and the daughters also developed occasionally an ulceration of the lining of the mouth, most probably due to some obscure nervous cause A young man suffered from retention of urine after seeing his father catheterised for this condition A catheter was passed and drew off two drachms of urine (Dr A Lomas's case) —Dr A Wallace, Dr J A Menzies, and Mr H H I Hitchon joined in the discussion on the paper

THERAPEUTICAL SOCIETY —A meeting of this society was held on Dec 22nd, 1903, Dr Clarence Cooper, Master of the Apothecaries' Society, being in the chair —Dr W E Dixon read a paper in which he described the Action of Drugs on the Pulmonary Vessels He showed that these vessels had no nerve supply so that drugs which contracted ordinary systemic vessels did not affect those of the lungs He divided the drugs into three groups, the first of which included pilocarpine, adrenalin physostigmine, and digitalis which acted on peripheral nerve endings and produced marked contraction in systemic vessels but had no action on pulmonary vessels The second group consisted of substances such as barium and calcium salts and veratrine which acted directly on the muscles and produced contraction not only in the systemic but also in the pulmonary vessels The third group consisted of substances such as the nitrites and caffeine which caused vaso dilatation and acted not only on the systemic vessels but also on those of the lungs and must therefore affect directly the muscular tissues of the vessels In conclusion Dr Dixon explained how such substances as digitalis and adrenalin gave rise to marked pulmonary congestion —Dr H Sainsbury, Dr F de Havilland Hall and Mr E D Vinrace took part in the discussion —Mr Vinrace read a paper entitled "A I I a for the

More Thorough Study of Therapeutics." He said that little attention was now paid by medical students to therapeutics which in examinations had not the same importance as pathology or bacteriology. Young practitioners were therefore not so well qualified as they might be to treat minor ailments; the sufferer accordingly often sought advice from a druggist and finding relief continued to consult him in more serious diseases. Unfortunately, also, medical practitioners had in many cases given up dispensing their own medicines and even the art of writing prescriptions was on the wane, as many medical men now depended on the wholesale druggists for the supply of remedies ready prepared for use which the patient might afterwards obtain for himself in other ailments, whether similar or not, without consulting a medical man, thereby running great risks.

Reviews and Notices of Books.

Doctors and their Work; or, Medicine, Quackery, and Disease. By ROBERT BRUDENELL CARTER, F.R.C.S. Eng., Knight of Justice of the Order of the Hospital of St. John of Jerusalem in England and Consulting Ophthalmic Surgeon to St. George's Hospital and to the National Hospital for the Paralysed and Epileptic. London: Smith, Elder, and Co. Pp. 316 Price 6s.

Mr. Brudenell Carter's aim in taking up his pen has been, as he indicates in his preface, to bring about a better understanding of medical objects and methods than now commonly prevails and to show patients in which way they can coöperate with their physicians for the relief of suffering and the prolongation of life. His intentions have resulted in a thoroughly good and interesting book and we have great pleasure in commending it to all our readers. We hope also that it may have the wider circulation outside the medical profession for which its author destines it, for a perusal of its contents will enable thoughtful members of the public to appreciate the difficulties and the responsibilities of the *vita medica* in a manner that, alas, few of them now do. Mr. Carter is a man of wide experience and strong views, and his habit of clear and exact writing enables him to place his knowledge and opinions in an uncompromising manner before his public. No one can misunderstand a word of what he writes, while the personal note of the book is struck on the title page by the adoption of Montaigne's well-known motto "*J'ay faict ce que j'ay voulu: tout le monde me reconnoit en mon livre, et mon livre en moi.*" It is possible that some who have considered the various social and ethical problems presenting themselves as incidents in our professional life will not agree with Mr. Carter in every detail, but in general we think that all medical men will find themselves in accord with one whose sense of the dignity of medicine is so marked, and whose moderation and fairness are in evidence throughout, however vigorous he may be in adopting an individual line.

A brief introductory chapter traces the history of the medical profession in England and shows incidentally that the troubles connected with the title of "Dr." were existent half a century ago, as they are now. From these troubles, acting of course simultaneously with other and more obvious factors, arose the movement for the reformation of the medical profession which culminated in the Medical Act of 1858. Previously to the passing of that Act in England the style of M.D. was to a great extent reserved for doctors of medicine of the Universities of Oxford and Cambridge whose intention it was to practise as consultant physicians; but in Scotland and Ireland, where the medical graduates had no legal status for practice in England, the title of "Dr." was earned and used by general practitioners. It became, therefore, the habit of certain English practitioners to acquire the degrees of Irish and Scotch, especially of Scotch, universities, and in those days such degrees were sometimes to be obtained with regrettable facility. The Scotch M.D.'s would then reappear in England with the style which in England was regarded as a hall-mark of the consultant physician, although there was nothing in their professional career which marked them as different from the holders of the diplomas of the English corporations. Obviously only a general standard of medical education for all the medical men of the kingdom could remedy an abuse which tended towards down-grade competition among educational bodies, and to enforce such a standard was a powerful reason for the constitution of the General Medical Council which came into being on the passage of the first Medical Act. Of the other causes which led to the passing of the Act under which, with but minor modifications, we at the present day pursue our professional calling, Mr. Carter does not say much, while the actual condition of medical education as it to-day exists under that Act, and the supplementary Act of 1886, he regards without enthusiasm. For many years representative of the Society of Apothecaries of London upon the General Medical Council he has had first-hand chances for forming an opinion upon the subject, and it is clear that he would have the preliminary education of the medical student considerably modified. The early training of the medical student, especially of the London medical student, whose academic opportunities are as poor as his clinical opportunities are rich, is at the present moment giving serious concern to the General Medical Council, to the authorities of the University of London, and to the teaching staffs of all the big hospitals. Neither the public nor the medical profession ought to continue ignorant of the questions at issue and in Mr. Carter's book they will find, not only in the introduction but in every chapter, information germane to the subject.

Two excellent practical chapters are headed "Reasons for Success and Reasons for Failure in the Medical Profession" Mr. Carter inevitably quotes Sir James Paget's well-known inquiry into the after-careers of a thousand students at St. Bartholomew's Hospital, and by closely analysing the figures of the famous surgeon and teacher comes to the conclusion that the medical profession offers as fair a chance of what is generally considered professional success as any other calling. But he goes on to point out as a singular fact in sociology that the mental attitude of the public towards medicine is credulous and superstitious, very much in fact resembling the attitude of the professors of medicine themselves towards their art 300 years ago. In a humorous and caustic chapter he shows that the public at large have not grown intellectually with their medical men in their conception of the aims and powers of the healing art. The half-education of to-day leads many to quote with facility what are mere nursery axioms in respect of disease and, alas, leads them to expect from their medical advisers some kind of endorsement of the obsolete lore. Many patients are still pleased to hear that their cataracts are not "ripe" for treatment or that their headaches are "latent gout"; the man who knows that his "blood is heated" or that he is suffering from "liver depression" is still quite common in our consulting rooms. He is urgent in demanding that something should be given him for the condition, and the course thereupon to be adopted by the honest practitioner towards him is a difficult one. "The patient whose chief desire it is to recover from his malady," writes Mr. Carter, "and who as a means of attaining that primary object desires to do all that is within his power to contribute towards its attainment, will usually act wisely if he abstains to seek popular explanation of physiological doctrine, and is content to submit himself resignedly into the hands of the doctor whom he has selected, and in whom he has confidence, and to do and avoid what he is told to do or to avoid without disturbing his mind as regards either nomenclature or causes." Quite so, but this excellent class of patient is in daily practice counterbalanced by the other class that desires to be treated according to its folly. It is not possible to lay down any general rule for the guidance of the medical practitioner and Mr. Carter does not attempt to do so. He contents himself with giving a clear account of how and why the position arises.

We need give no further detailed account of "Doctors and their Work." Under the head of "Medical Grievances" we find a spirited appeal to medical men not to class themselves as tradesmen. Mr. Carter's contempt for the "eminent doctor" whose fame is established in the boudoir or by the society journal and his appreciation of the mental deficiencies of "anti's" make excellent reading, and he tells the story of "medical etiquette" in a dozen pages of common sense. We commend the book heartily to our readers and we hope that the public will also study it. In a leading article at the beginning of the new year we urged that the aims of the profession and the public were broadly the same, and that apparent antagonism would often cease if the laity were better instructed upon professional matters. From this point of view Mr. Carter's book is very opportune. His design in writing it has been to assist a *rapprochement* between the medical man and his patient upon grounds of mutual esteem, and his method of execution is well calculated to bring about his commendable object.

The Standard Medical Directory of North America 1903–1904. Chicago: G. P. Engelhard and Co. Pp. 1226 Quarto.

THIS medical directory of North America includes not only the names of practitioners in the United States of America, whether in civil practice or employed as officers in the United States army or navy, but also the names of all practitioners in Canada, Cuba, Mexico, and Central America. Full information is given in addition concerning the medical laws and the constitution of any governing bodies of the profession in the different countries; there are accounts of medical societies and medical educational bodies, classified lists of medical books and periodicals, and notes upon various hospitals and sanatoriums It will be gathered from this that the work is an enormous book of reference and it must have entailed much and serious labour upon its compilers.

The list of medical colleges of North America shows that those responsible for this directory are not scrupulous to apply the word "medical" only to studies that are scientifically medical. Eclectic and homœopathic educational centres are set down as places where medical education can be obtained. This uncritical attitude is more or less forced upon the producers of an American medical directory, as it is clear that any one having a legal status upon which to practise has a right to insist that his name should appear in what must be regarded as a semi-official list of members of the medical profession. In England we see the names of members of the medical profession upon the Medical Register who do not practise in accordance with the scientific teaching and system under which they obtained their qualifications. It is true that in America, apparently, examinations are recognised by certain States which are conducted upon eclectic or homœopathic methods, whereas in this country the standard of medical education exacted by the General Medical Council compels every medical student to be instructed up to a certain point in scientific medicine. Nothing, however, prevents a man, after his qualifications in scientific medicine have gained him a place on the Medical Register, from becoming a homœopath, so that our Medical Register is no more pure of heretics than is the North American Directory, although the presence of dissentient names has a different explanation.

The bulk of the book is, of course, taken up by the names and addresses of the medical men in North America. Upwards of 1000 quarto pages are filled with the names arranged in four columns of tiny print. The names are first entered under addresses in the United States; then come the Central American States and Cuba; and then the Dominion of Canada. In the next section all these names are entered alphabetically, having placed against them their addresses. A great deal of space is saved in giving the qualifications by using an elaborate system of abbreviations For instance, we find a gentleman in the alphabetical index entered as, say, Smith, J. H., Palo Alto, California We turn up the place and find Smith, J. H., Ont. 5, '92. We then look up Ont 5, which signifies the fifth in the list of the medical centres of Ontario and thus ascertain what are the qualifications of Mr. J. H. Smith to practise, '92 signifying that these were obtained in 1892. A weary repetition of similar titles appended after thousands of names is by this simple plan rendered needless. We have said enough to show that we consider the "Standard Medical Directory of North America" a thoroughly useful and carefully prepared book of reference. We hope that the great American public, so devoted to quackery and all forms of irregular medical practice, will get into the way of consulting the directory before consulting the individual. There is nothing over discriminating about the directory, as we have indicated, and if a physician's name is not found in its generous pages he should not be called in.

LIBRARY TABLE.

Cancer and Pre cancerous Changes: their Origin and Treatment By G H. FINK, M R C.S Eng, L S.A. Lond., Major, Indian Medical Service (retired). London: H. K. Lewis. 1903 Pp. 105—This book is intended to assist in the investigations at present in progress into the origin of malignant disease and its treatment, both preventive and remedial. The author discusses all the main theories hitherto advanced to account for the origin of cancer. He then enters on a thorough investigation of the life-history of many animal and vegetable parasites and, as he has read very widely, this portion of the work is of great interest. The conclusions at which he arrives are that there are many points of resemblance between cancer and malaria, though the former is more prevalent in temperate climates and the latter in tropical regions, therefore he is inclined to look upon cancer as parasitic in origin The author, however, lays great stress on the necessity for predisposing factors in the body of the host. The treatment advocated naturally follows the lines suggested by the theory of causation advanced. For the prevention of cancer a simple healthy life without excess of diet will tend to prevent any predisposition; the surroundings should be healthy and as the author considers it probable that the "germ" may be conveyed by an insect he advises that flies and other insects should be excluded from dwellings Great care should also be bestowed on the water supply and the water should be boiled or filtered before use. The treatment after the appearance of the disease consists in attention to the *primæ viæ* and care as to food and perhaps the employment of sera from cases of rodent ulcer and lymphadenomata. The book is evidently the outcome of much thought and deserves consideration.

Diseases of the Skin: an Outline of the Principles and Practice of Dermatology. By MALCOLM MORRIS Consulting Surgeon to the Skin Department, St. Mary's Hospital, London, &c. With two Coloured Plates and 58 Plain Figures. New edition. London, Paris, New York, and Melbourne

Cassell and Company. 1903 Pp. 642. Price 10*s.* 6*d.* net.—Ten years have elapsed since the appearance of the first edition of this well-known text-book and we extend a cordial welcome to this issue. Of the smaller manuals of dermatology this is probably the most suitable for general use, for it is sufficiently full for the purposes of the average student and practitioner and yet its bulk has not been needlessly increased by the inclusion of details which are of interest to the expert only. In such a subject as dermatology, pervaded as it is with questions still undecided, there is an abundance of material for differences of opinion and there are many points on which we might join issue with Mr. Malcolm Morris but we must acknowledge that the views put forward in this work are, on the whole, those generally accepted. There are numerous illustrations and most of them show clearly what they are intended to represent.

The Royal London Ophthalmic Hospital Reports. Edited by WILLIAM LANG, F.R.C.S. Eng. Vol. XV., Part 4. October, 1903. London: J. and A. Churchill.—The contents of this part of the Royal London Ophthalmic Hospital Reports are as follows: 1. Some remarks on the Use of Mallory's Phosphotungstic Acid Hæmatoxylin and a note on the Musculus Papillæ Optici of Nicolai, by F. H. Verhoeff, M.D., pathologist to the Massachusetts Charitable Eye and Ear Infirmary, Boston, U.S.A. Details are given of the action of Mallory's and Zenker's fluids and of formaldehyde and nitric acid with thorough washing with water. The author denies the existence of Nicolai's muscle, believing the supposed smooth muscle cells to be really neuroglia elements. He gives a plate in which are drawings illustrative of his own views. In an appendix to the above article he describes a hitherto overlooked membrane of the eye. This is a fenestrated membrane situated in the pigment layer of the retina, identical in structure and staining reactions with the membrana limitans externa The rods and cones are not, in his opinion, nervous elements but modified ependymal cells. 2 Observations on Renal Retinitis, by E. Nettleship, F.R.C S. Eng. This is a record of the results of the observation and post-mortem examination of many cases of retinitis. Mr. Nettleship states that the microscopic features and micro-chemical reactions of the brilliant white spots seen on the retina show that they are not, as has been generally accepted, fatty exudations, but that they are either amorphous or composed of a fine fibrinous network. 3. Epithelial Plaques of the Conjunctiva, by W. T. Lister, F.R C.S. Eng., and W. Ilbert Hancock, F.R C S Eng. These growths are rare. Examination under the microscope in four instances showed that the growth consisted of a mass of epithelial cells and was nearly avascular. 4. A Pathological Report on a case of Mooren's Ulcer of the Cornea, by W. T. Lister, F.R.C.S Eng. 5. Two cases of Pigmentation of the Retina, by E. Erskine Henderson, F.R C.S. Eng., with a plate. 6. A case of Orbital Wound in which the Optic Nerve and Central Retinal Vessels were divided, by J. Herbert Parsons, F R.C.S. Eng, curator of the Royal London Ophthalmic Hospital Museum, with a plate; also (7) by the same observer a case of Epithelial Hyperplasia of a Ciliary Process. 8 Acute Dacryo adenitis, by William S. Inman, M.B. Lond., senior house surgeon, Royal London Ophthalmic Hospital. Dr. Inman reports ten cases as having occurred amongst the patients of the hospital in two years and refers to the literature of the disease. He draws the conclusion that the cases may be arranged in two groups, those associated with mumps which are usually bilateral and in which suppuration does not occur, and those not associated with mumps, in which the disease is usually unilateral and suppuration may or may not occur. This part contains the index to the fifteenth volume of the Reports.

FOURTH REPORT OF THE ROYAL COMMISSION ON SEWAGE DISPOSAL.[1]

POLLUTION OF TIDAL WATERS WITH SPECIAL REFERENCE TO THE CONTAMINATION OF SHELL-FISH.

THIS report, which consists of 54 pages, is a document of very far reaching import and its influence will be felt much beyond the limits to which it nominally applies. As we are discussing the general aspects of the problem in a leading article we shall confine ourselves in this place to a general *résumé* of the contents of the report. After their introductory remarks the Commissioners refer somewhat critically to

The Laws in regard to the Pollution of Tidal Waters.

Under this heading they show that although Section 17 of the Public Health Act, 1875, confers certain powers with regard to the prevention of the pollution of non-tidal waters its provisions have not hitherto been interpreted as applying to tidal waters, and very much the same remark may be made in respect of the provisions of the Rivers Pollution Act, 1876, which exempts tidal waters from its operations unless after inquiry by the Local Government Board any given tidal estuary is declared to be a "stream" within the meaning of the Act. As a matter of fact such a declaration has been but rarely made and the instances thereof could probably be counted on the fingers of one hand. Similarly, in regard to the Salmon Fisheries Acts of 1861 and 1862, it would seem that in order to take successful action under their provisions it is necessary to prove that "the pollution complained of has poisoned or killed fish," and an occurrence of this nature is a very different thing from the specific pollution of water by sewage. Lastly, it would appear that the Sea Fisheries Committees are unable to obtain any relief under the powers of their by-laws, since nothing in the Sea Fisheries Regulation Act, 1888, "shall authorise ...... a by-law affecting any powers of a sanitary or other local authority to discharge sewage in pursuance of any power given by a general or local Act of Parliament" The Commissioners raise the question as to whether the Board of Trade in taking the view that this proviso renders the by-laws inapplicable to the discharge of sewage by local authorities has correctly interpreted the law, but the Commissioners are nevertheless forced unwillingly to the conclusion that the statute does not in practice prohibit the discharge of polluting matters into tidal waters.

The Extent of the Mischief Caused by Polluted Shell fish.

With the view of obtaining assistance in their researches the Commissioners, through their secretary, Mr. F. J. Willis, despatched a circular letter to the county council of every county in England and Wales having any sea-board, and it is of interest in obvious directions to be able to narrate that of the 31 county councils thus addressed 21 had no evidence to offer on the questions raised. The remaining county councils sent copies of reports made by local medical officers of health or furnished other information which had been brought to their notice. Numerous witnesses representing public health, bacteriology, and the shell-fish industry were examined and the Commissioners themselves visited oyster layings and mussel and cockle areas throughout the country. They also carried out most important scientific researches to which reference will be made subsequently. As regards the fact that enteric fever and other illnesses may be caused by the consumption of specifically polluted shell-fish the Commissioners express themselves as fully satisfied, and they refer particularly to the remarkable outburst of illness which followed the mayoral banquets at Winchester and Southampton as an illustration of the danger which the public run under the present uncontrolled conditions. In dealing with the proportion of enteric fever generally which may be attributed to the consumption of polluted shell-fish reference is made to the evidence of Dr. J. T. C Nash of Southend who thinks that in Southend at least 50 per cent. of the cases in 1902 were due to this cause, of Dr. A. Newsholme who puts the proportion in Brighton between 1894–1902 at 37 per cent, of Dr. J. Niven who thinks that in Manchester an estimate of 10·3 per cent. understates the case, and of Mr. Shirley F. Murphy who inclines to the view that in 1902 the 8 per cent. of the enteric fever occurring in London which was associated with the eating of shell-fish at a time consistent with the incubation period of the disease is probably an under-statement of such an association. As a result of all the evidence put before them under this head the Commissioners do not feel justified in making an estimate in regard to the country as a whole and herein they doubtless show their wisdom. They are, however, unanimous that the evil demands a remedy not only in relation to the interests of the public health but also in that of the shell-fish industry. Passing to the

---

[1] Fourth Report of the *Commissioners appointed* in 1898 to inquire and report what methods of treating and disposing of sewage may properly be adopted Eyre and Spottiswoode, East Harding-street, Fleet street, E.C. Price 4½*d.*

Remedies Suggested,

the Commissioners in discussing the purification of sewage raise a question which is of the greatest importance to a proper understanding of the problem. They point out that in their interim report of July 12th, 1901, they drew attention to the fact that the effluents from sewage farms as well as effluents from artificial purification processes usually contain large numbers of micro-organisms, many of which appear to be of intestinal derivation. Their subsequent investigations have only tended to confirm this conclusion and they tell us that the microbe of green pus which was added to sewage in large numbers by Dr. A. C. Houston passed freely through sewage purification works consisting of (1) septic tank and contact bed; and (2) continuous filter about ten feet in depth. What, therefore, it comes to is that no known *practicable* means of [illegible] organisms [illegible] : the better [illegible] situation. But the Commissioners are, nevertheless, not without hope that some method of sewage treatment may be devised by which *within reasonable limits of cost* (herein is the crux of the situation) the dangerous qualities of sewage may be eliminated.

With respect to the seizure of unwholesome shell fish the Commissioners agree with the evidence given by Dr. Newsholme that the existing provisions are practically useless for preventing the sale of contaminated shell-fish, and the prosecutions which have recently taken place in the City do not, unfortunately, alter the situation; indeed, they somewhat complicate it. They do so since, in the opinion of the Commissioners and as the result of the researches which they have made, they have been forced to the conclusion that bacteriology at present cannot be relied upon to determine whether oysters or other shell-fish are or are not polluted. Certain of the witnesses urged upon the Commissioners the desirability of ascertaining the distribution of the bacillus coli in the animal kingdom, as it seemed to them possible that further knowledge might invalidate the conclusion that "the normal oyster does not harbour within its shell or within its body bacillus coli communis or other B. coli closely allied to it," a basis upon which apparently oysters have in the past been condemned by those bacteriologists who believed that bacteriology could, apart from all other considerations, be relied upon as an index of pollution. In order to clear up this important point Dr. Houston examined a very large number of oysters procured from all sorts of layings around the coast and his researches revealed the eminently disturbing fact that in oysters taken from the various layings the number of bacilli coli or bacillus "coli-like" microbes varied in an oyster from 10 to 10,000, and it also appears, contrary to what has been formerly taught, that far more bacilli coli were found in the contents of the stomach than were found in the liquor contained between the shells. It is, however, very necessary to point out that, *taking in each instance the whole oyster*, a very much smaller number of bacilli coli or bacillus "coli-like" microbes is found in oysters stored in pure water than in oysters stored in polluted waters. But the Commissioners do not see their way to lay down any standard in the matter and they add very significantly, "If it should be seriously contended that the mere presence of bacillus coli or coli-like microbes in an oyster should condemn it few oysters would probably escape condemnation. This is a point to which we shall return, but we may at once state that we see no justification for such wholesale condemnation." They also direct attention to the eminently misleading conclusion which may be drawn from a chance sample of oysters or water.

With regard to the bacterial flora of sea and estuary waters numerous samples have been examined and it is most instructive to learn from Dr. Houston's work that of 34 samples of deep-sea water collected on the north-west coast of Scotland within sight of land but remote from pollution none contained bacillus "coli-like" microbes of any sort when using 100 cubic centimetres of water. The inference is that these microbes form no essential part of the bacterial flora at the surface of deep-sea waters at a distance from land and similar results and conclusions were obtained with bacillus enteritidis sporogenes. It has been contended by some that the deposit of the London sewage sludge in the Barrow Deep was causing grave evils and hence the statement that in Barrow Deep one half of the samples of water tested were not found to contain one bacillus coli per cubic centimetre will come somewhat as a surprise. This is a state of affairs which, we believe, is not excelled by the upper Thames in the vicinity of the intakes of the London drinking water.

In summing up their conclusions as to the bacteriological portion of their labours, and what these have really been can only be duly appreciated when the appendices containing the evidence and the record of the research work are issued, the Commissioners quote from the evidence of Dr. Klein to this effect: "Dr. Klein has repudiated the notion that shell-fish could be condemned solely on account of detection in them of the presence of B. coli. He said, 'I myself would not countenance this without the knowledge of the topographical conditions'; and again, 'I would not myself reject oysters as polluted with human sewage on account of the purely bacteriological examination.'" The Commissioners add: "We are aware that this view of the present limits of bacteriology as applied to shell-fish has not been uniformly acted upon, but we see no reason to doubt that it is in the main correct and that it should be accepted for the purpose of present administrative action." With regard to what may be called the "proportion" test concerning which we have heard much of late, the Commissioners state: "Mere numbers of B coli or any other particular micro-organism of sewage cannot, therefore, be said to have anything approaching an exact value as an indicator of the danger of disease and we consider that before any working bacteriological standard can be applied to this problem further knowledge is necessary" We cannot spare more space for a consideration of this absorbing topic and we must conclude this notice with a brief reference to the recommendations of the Commission.

After discussing numerous alternative proposals the Commissioners state that after carefully considering the whole of the evidence together with the teachings of their own researches and inspections the only way in which, in their opinion, the evil can be effectively dealt with is to place tidal waters under the jurisdiction of some competent authority. They propose to confer upon such authority power to prevent the taking of all forms of shell-fish for human consumption from any position in which they are liable to risk of dangerous contamination and to enforce restrictions as regards

Boards should be fully equipped in a scientific sense to deal with the problems which will arise from time to time. The procedure to be adopted by this controlling authority is to consist of a survey of each district, of a registration of pits, ponds, beds, layings, and the like, and of a prohibition of certain prescribed areas as those from which no shell-fish of whatever nature may be collected for human consumption. The Rivers Boards are, too, to determine in what cases the treatment of sewage is likely to render the conditions safer; they are to control the construction of fresh sewer outfalls and oyster ponds and generally to supervise the sanitary condition of our estuaries. As regards foreign shell fish the Commissioners advise that for the present a guarantee should be required on the part of each Government concerned "that all oysters or other shell fish imported into this country for human consumption had been procured from localities where they were not liable to be contaminated by sewage or other objectionable filth" and they think that in addition the Government of each country exporting shell-fish to Great Britain should be requested to grant facilities to an accredited representative from the central authority presiding over the Rivers Boards in this country to inspect at intervals the layings, ponds, and other places from which shell-fish are exported into this country. Failing such guarantee and permission all foreign shell fish for human consumption are to be deposited in registered layings or non prohibited areas in this country for a period of not less than six weeks antecedent to their disposal on the market.

THE LANCET.

LONDON: SATURDAY, JANUARY 16, 1904.

The Control of Home and Foreign Shell-fish.

THE fourth report of the Royal Commission on Sewage Disposal, which we notice in some detail in another part of our present issue, has been drawn up by persons able to take both a scientific and a statesman-like view of the problem. From a purely scientific standpoint the report is remarkable in that for the first time in the history of bacteriology a check has been administered to that young and vigorous pursuit which will result in an improvement of its methods and in more guarded interpretation of its rapid unfolding of nature's story. It is fortunate for the real progress of bacteriology that Lord IDDESLEIGH'S Commission numbers amongst its members such men as Sir MICHAEL FOSTER, Mr. W. H. POWER, Sir WILLIAM RAMSAY, and Dr. J. B. RUSSELL of the Scotch Local Government Board, since they have by their investigations, in spite of the critical attitude to which we have alluded, been able to advance materially certain aspects of the bacteriology of shell-fish and of sea water.

The Commissioners have not unexpectedly come to the conclusion that a real *danger exists* from the consumption of oysters, mussels, or cockles procured from sources more or less obviously liable to pollution by sewage, and they have recognised that in addition to enteric fever a considerable amount of other illness, such as gastro enteritis, may be caused by such a diet. In setting themselves to devise a remedy for the existing state of affairs it was natural that they should have turned their attention in the first instance to that relatively modern science the application of which has been fraught with such blessings to humanity in the treatment and prevention of disease and in perfecting or improving our industrial processes. It was hoped that by bacteriology we might be able to recognise polluted or dangerous shell-fish and hence to fix standards which might guide and control administrative action. But, as the chemist in his domain has been unable to tell us with certainty of the dangers which beset our water-supplies, even so the bacteriologist has failed to prove a trustworthy guide in this particular department of biology. Hitherto the bacteriologist has in practice apparently acted on the assumption that "the *normal* oyster does not harbour within its shell or within its body bacillus coli communis or other B. coli allied to it" and hence he has inferred that the "presence" of the bacillus coli communis "in considerable numbers of oysters in a *series of* samples from a particular locality may be taken to indicate sewage pollution." But it was suggested to the Commissioners by Dr. H. T. BULSTRODE and Dr. J. C. THRESH that possibly the premiss upon which this inference was based might be usefully verified. Accordingly Dr. A. C. HOUSTON was instructed to make a thorough investigation into this subject and as the results of such researches it was found that "nearly all oysters so examined from whatever laying they were taken contained bacillus coli communis or other B. coli allied to it." It seems, indeed, that when a quantitative examination was made the number of bacillus coli or bacillus coli-like microbes varied in an oyster from 10–10,000, the number of the bacilli coli contained in the stomach being greater than that in the liquor contained in the shell. The Commissioners state that the investigation has been carried out by Dr. HOUSTON in the most careful manner and that more than 1000 oysters have been examined. It would seem, too, from the evidence of Dr. THRESH that cockles obtained from places far removed from any ascertainable source of pollution may contain the bacillus coli. There are, however, certain conclusions arrived at by Dr. HOUSTON which it would be obviously unfair to bacteriology to omit to mention and in fact the Commissioners draw special attention thereto When the whole oyster is examined, a much smaller number of bacilli coli is found in oysters stored in pure water than in oysters stored in polluted waters, and, moreover, it seems probable that deep-sea oysters are free from either the bacillus coli or similar organisms. So, too, in regard to sea water it has to be recorded that no bacillus coli-like microbes of any sort, even in 100 cubic centimetres of water, were found in samples collected within sight of land on the north west coast of Scotland. But the Commissioners have gone very thoroughly into the whole question and the conclusion to which they are forced by the researches of Dr. HOUSTON and Dr. E. J. MCWEENEY, and by other evidence is that they would "not be justified in recommending that the closing of a foreshore, laying, or pond should depend *as a matter of routine* on the results of bacteriological examination." And we must confess, unwilling as we are to accept the situation, that we fail to see how on the evidence they could possibly arrive at any other conclusion. They add, "if it should be seriously contended that the mere presence of B. coli or coli-like microbes in an oyster should condemn it few oysters would probably escape condemnation ..... we may at once state that we see no justification for such wholesale condemnation," and they quote Dr. E. E KLEIN to the effect that "I could not myself reject oysters as polluted with human sewage on account of the purely bacteriological examination." The Commissioners are, however, not without hope that further research may enable bacteriology to prove of very material assistance.

Passing from this to other measures the Commissioners point out that, in the great majority of cases in which outbreaks of disease have been at all clearly traced to *shell-fish*, the foreshores, layings, or ponds from which the shell fish have been procured have been found to be so situated that the opportunities of pollution by sewage have been obvious; and they think that, although it is not at *present* possible to define with certainty the limits of the danger, if those places were closed or freed from chances of pollution the greater number of cases of disease due to the consumption of contaminated shell-fish would be eliminated. In their view the first step should be to deal with those foreshores, pits, ponds, beds, or layings of which the pollution is obvious and indisputable, and in this connexion the able cross-examination of Mr. SHIRLEY

MURPHY by Mr. T. J. STAFFORD, a member of the Commission, is well worth perusal. In discussing the authority by which the registration and the control of shell fish layings should be administered, the Commissioners pass in review previous proposals and they finally arrive at the conclusion that the Rivers Boards, the creation of which they recommended in their third report, would prove by far the most suitable bodies not only in regard to administrative action but also with respect to the prosecution of the necessary scientific research. These boards would be under the supervision of a central board and they would have the right to prohibit the gathering or laying down of *any* shell-fish within such limits as they might from time to time prescribe. They would also have control over all estuaries within these large areas, each board probably comprising several counties, and would regulate all questions relative to the discharge and purification of sewage or other filth. These and other measures proposed by the Royal Commission are, in our view, framed with an earnest desire to put an end to the present unsatisfactory state of affairs without at the same time depriving thousands of persons in this and other countries of their habitual means of livelihood. The machinery suggested would obviously be capable of expansion with growing knowledge and experience, and the measures proposed would, if acted upon, put an end to public risk as well as to the depression in a valuable industry. If this chance is lost it may be years before any definite and comprehensive action is again possible. It is earnestly to be hoped that the shell-fish industry will unite with the public health service in a vigorous combined attempt to place the recommendations of this Commission upon the statute-book. If this is to be done in the ensuing session there is no time to be lost.

The Edinburgh Royal Infirmary: the Question of Superannuation.

AT the recent annual general meeting of the court of contributors of the Royal Infirmary of Edinburgh some very important principles were discussed and some resolutions were carried which are likely to create a great deal of friction. Our readers are referred to an article upon the matter from a correspondent which appears on p. 180, and in which no attempt is made to disguise the writer's views. The proceedings at the meeting opened with the usual annual report of the managers dealing with the number of patients treated, and with details of income and expenditure, and kindred subjects. It was then stated that the managers had introduced a new rule to the effect that the ordinary physicians and surgeons should retire in future on attaining the age of 65 years but that this rule should not be applied in the case of those members of the staff who were at present serving their second or third term of five years in charge of wards or to the professors of the University of Edinburgh. It could scarcely be expected that such a curious and partial alteration in existing regulations would be allowed to pass unchallenged, since, if compulsory retirement is desirable, such change should only affect those who undertake office under the new regulation. All who are already in office should be upon an equal footing and there would thus seem to be no reason for making any distinction between those who have been appointed during the last five years and those who are serving their second or third term of five years. Under former regulations members of the ordinary staff are only appointed to charge of wards for 15 years, and this rule was enforced, although in exceptional circumstances it might lead to retirement at a comparatively early age.

It will be noted that the new regulation, as drafted by the managers expressly exempted the professors from its operation, and in relation to these distinguished gentlemen it should be borne in mind that the staff of the Edinburgh Royal Infirmary is composed of members who may or may not have other teaching duties in the School of Medicine of the Royal Colleges of Edinburgh, and of certain professors of the University of Edinburgh who are nominated by the University as physicians and surgeons of the institution, and who are thus afforded facilities for giving clinical instruction in medicine and surgery. The discussion at the meeting turned mainly upon the proposed establishment of an age limit for the professors as well as for other members of the staff, and it is instructive to consider the arguments adduced by those who favoured and those who opposed the new proposal. In the first place it was definitely stated that it was not proposed to enforce the age limit upon the present professors but merely to establish a rule for future guidance. On grounds of efficiency it was urged broadly that a time came, even to the most skilful, when keenness of vision, delicacy of touch, and firmness of nerve gradually deteriorated, while there would also be inability to answer the emergency calls that might come at any hour of the night. Assuming the truth of the foregoing arguments one speaker said he felt a serious doubt as to whether there was anything exceptional in the case of the University professor which should exempt him from the rule which had been found necessary in the case of the ordinary physician and surgeon. With grave irony he presumed that the University professor was subject to the common rules of life and that old age grew on him as much as on any other man. Since the infirmary patients could not choose for themselves the medical men to whom they were going to intrust their lives and health it was felt by the managers that they had a public duty to perform in providing for efficient service. In spite of compliments paid to the present brilliant and distinguished body of professors, past experience afforded instances of some who had held their position in the Royal Infirmary beyond the age when they were completely qualified for work there. Against the proposal it was argued that the work of the University might be much hampered by this new regulation, that on other grounds the University might desire to appoint professors who would not be eligible to have wards in the infirmary, and that the area of selection of candidates for professorial chairs would be narrowed since candidates might be unwilling to come forward. Some speakers doubted the propriety of intimating to the University that any professor appointed with clinical teaching in the infirmary could only be accepted on the footing that he was to retire from those duties at the age of

65 years. In spite of all these arguments, and in spite of an amendment proposing to remit this question to the managers for further consideration and for report at the annual meeting in 1905, it was ultimately decided to establish the age limit of 65 years for all members of the staff with the exception of the present professors and of those ordinary members who are serving their second or third term of five years in charge of wards.

It must be admitted that the effect of this resolution is likely to produce curious results, since the Edinburgh Royal Infirmary thus criticises the action of the University and assumes the right to question the wisdom of its appointments, while it indirectly suggests the advisability of an age limit of service in the University as well as in the infirmary. There can be no doubt as to the injustice of the arbitrary distinctions made amongst the existing members of the staff of the infirmary. The new regulation should only apply to those who are appointed to office subsequently to its enactment, since those who have already been engaged in the work of the Royal Infirmary presumably undertook their arduous duties after full consideration of their prospects of advancement under existing regulations. It appears to be a breach of good faith to alter the terms of office which may have tempted them to endure the weary waiting in the out-patient room in the hope of ultimately succeeding to a reasonable period of ward work. There is, on the other hand, much to be said in favour of the establishment of an age limit of hospital service since it often affords an opportunity of graceful retirement when the demands of private work are impeding the due performance of hospital duties. In the interests of the patients in the hospital it might even be desirable that the age limit should be fixed somewhat earlier for surgeons than for physicians, since, while the former have been enduring considerable physical strain, the latter have been accumulating experience which renders their opinions valuable so long as they are able to retain their faculties and to maintain their interest in scientific progress. From a practical side, however, it will probably always be difficult to establish any such distinction between the two chief branches of professional work, and endless confusion might result from any attempt to differentiate between obstetric physicians and surgeons or those in charge of other special departments. Whether university professorships should be subject to age limitations is perhaps too difficult a question to determine, since it so largely depends upon the duties demanded. Many such appointments are regarded as posts of honour and reward for previous work rather than as involving routine comparable to that required from a lecturer in a medical school. With this estimate of university professorships an age limit would defeat the main object of their creation.

◆

Slum Life in Birmingham.

THOSE who are only superficially acquainted with the problems of our great cities seem often to imagine that it is only in London that genuine slums occur. But the medical man and the sanitarian know well that Liverpool, Birmingham, and other great cities, as well as much smaller towns, can show areas worthy of entering into a disgraceful competition with the environment of "No. 5, John-street," areas of which the general public know nothing because they hear nothing, and of which they hear nothing because the *sacer vates* has been generally wanting. Concerning one of these slums some information has just been disseminated in the form of a little book by the gentleman who holds the cure of souls in what is known as the condemned area of Birmingham. Not for the first time in his present book[1] has Mr. BASS appealed to the public to turn their eyes upon the miseries in the midst of which he works, while the series of articles which appeared a few years ago in the *Birmingham Daily Gazette* revealed horrors which must have appeared inconceivable to those unversed in the annals of poverty and crime. A further pamphlet emanating from persons connected with the medical mission and alluded to in our Birmingham correspondence some months ago tells a very similar tale. Naturally, we may even say properly, both these productions were pitched in that somewhat high key which is necessary if the public attention is rapidly and certainly to be attracted but we doubt if, even so, they have had much effect. Broadly speaking, all that has been published about the slums of Birmingham was substantially accurate. This is proved by the sober words of an official report drawn up by Dr. ALFRED HILL who has just retired from the position of medical officer of health after 40 years of honourable service to the city of Birmingham. "The condemned area," he writes, "has a population of 2429 If the area allotted to dwellings only be taken into account the number of persons per acre is 272, as against 41 per acre for the whole city. As regards the mortality on the area, I find that in 1899 and 1900 the death-rate was 42·3 and 38·7 per 1000 respectively, giving a mean death-rate for the two years of 39·5. In the entire city the mean death-rate for the same period was 20·7 and in the entire wards of St. Mary's and Nechells—the two wards in which the area lies—it was 29·6 and 21·4 respectively." Further, he tells us that the houses in the condemned area smell offensively, are badly roofed, old, dark filthy, and in vile repair; that their privy accommodation is detestable and that they stand in unpaved courts. Of the 589 houses in the area 295 are back houses which open into inclosed courts, 250 of these 295 are approached by narrow tunnel entries so that there is practically no circulation of air around them, most of them are back to back with others, and 124 of the 294 front houses have no back-doors, so that these too have no proper ventilation. It is not surprising that Dr. HILL reports the area in question "an unhealthy area" and declares that "the evils connected with such houses and courts cannot be effectually remedied otherwise than by an improvement scheme for the rearrangement and reconstruction of some of the houses within the area."

Of the nature of the social disease thus made apparent there can be little doubt. It is a case where the diagnosis presents no difficulty but where the treatment to be resorted to is not to be decided upon easily or without forethought. The housing committee of the corporation of Birmingham has had the matter under consideration for a long time and has reported against the erection of municipal dwellings and in favour of opening up the courts so as to allow a little air to enter their noisome recesses. Mr. BASS thinks the proposals made are wholly inadequate; he points out that the back-to back houses are for the most part to be left untouched and that the pulling down of a house or two at the end of a court, though it may provide an air space and be of great service to the police in their work of supervision, does not do much to make the interior of the houses which are left more healthy than they were. Also, he points out that there are 6000 courts in Birmingham, that it is estimated that the expense of opening each of these up in the manner proposed will be about £100, and that consequently if only one in four is opened up the cost to the municipality will be £150,000 and at the end they will not possess a single rood of ground or shred of building to show for their expenditure. Moreover, it is pointed out that 100 courts have been dealt with in two years, at which rate of progress it will take 120 years to put all the courts in the city into the state suggested by the housing committee. All this is no doubt very true but this is a case where criticism is easy. Mr. BASS, from his point of view, is perfectly right to declaim against the present state of affairs and to denounce the corporation for what he considers to be its supine attitude in face of undoubted and terrible facts. But Mr. BASS's is not the only point of view from which the question—perhaps the most complicated question now before the municipalities of this country—has to be considered. In the first place there is the point of view of the landlord who claims, and with justice it must be said quite properly claims, that a great deal of the filth and insanitariness of the slum house is due to the conduct of its inhabitants. We are told of skirting-boards pulled down and banisters torn out for the purposes of making fires, of acts of carelessness and worse, all tending to make what was originally bad seven times worse than it was at first. Then there is this further point to be considered, that as soon as the landlord is compelled to improve his property and to spend money in so doing he endeavours to recoup himself by raising the rent. In this way he drives out the really necessitous person to make room for someone who is prepared to pay the higher charge, in which case the poorer man has to huddle into some other already overcrowded slum, or he compels the accumulation of two families in a house which formerly only held one. Mr. BASS would say that in such cases municipalities should acquire the land and build on it proper dwellings for the poor. It is not long since our Birmingham correspondent gave at length the reasons which actuated the housing committee of that city in refusing to take this step and the question of compensation for the landlords alone makes it a very difficult course. Moreover, the corporation would have to make a rigorous inquisition into the circumstances of each case that they might only admit to their dwellings the deserving poor, while criticism would not be wanting to point out that a certain number of wage-paying employers were having servants secured for them at a lower rate at the expense of the ratepayers.

---

[1] Hope in Shadow Land. By T. J. Bass. Birmingham Leicester: Midland Educational Co. Pp. 158. Price 1s net.

If the houses are to be built by the municipality they cannot be built, as municipal houses must be built, to pay their expenses at the rents which the very poor can afford to pay for them, when the expense of the ground is taken into consideration. Again, when a municipality enters upon a task of this kind all private efforts in the same direction come to an end. Now the exposure of the facts in Birmingham has at least led to the starting of two separate plans, on commercial lines, both of which we have described in our columns, the Rowton House and "Homes, Limited." The corporation is quite entitled to wait in order to see what effect these will have before embarking on a huge and costly scheme of clearance and rebuilding. With much that Mr. BASS says in his book we are in the most complete sympathy. We fully agree with him that to say, "Oh, it is all drink," or "It is the innate filthiness of the classes who inhabit these houses," does not justify the shelving of an enormously urgent social question. Drink may often be an effect just as much as a cause and when we see the places in which many of the poor live we cease to wonder that they seek relief from their misery and discomfort in the warm and cheerful gin-palace. Medical men are bound to endorse Mr. BASS's action in calling attention to the horrors amongst which he lives. Only by such plain speaking as he has employed can the public be aroused from their apathy. Medical men know of the existence of similar plague spots in most of our large cities but it is the experience of all sanitarians that until the time of epidemic arrives little attention is paid to these foci of disease and crime. They are regarded as inevitable products of the social scheme: they are shuddered at and forgotten. We believe that the conscience of Birmingham is fully aroused. The problem is pressing But to rush suddenly into a huge scheme without careful consideration would be a counsel of despair rather than of wisdom.

The Report of the Medical Officer of Health of the County of London.

WE have received the annual report of the medical officer of health of the county of London for the year 1902, which has been presented to the London County Council by the Public Health Committee, this being the eleventh annual report made by Mr. SHIRLEY MURPHY. As usual, the report bristles with figures, and also as usual, when we have Mr. SHIRLEY MURPHY's work to deal with, the figures are thoroughly explained, while many of the more important statistical points are accentuated and made easy of comprehension by charts and diagrams. At the first glance the reader may wonder why the report just issued should be dealing with 1902 and not 1903, but in our opinion no serious charge of procrastination can be made. The enormous population under the care of the London County Council, the magnitude of the questions in public health that are presented, and the careful manner in which the course pursued by the central health authority of the county is explained, sufficiently account for the delay. Such a report as the one before us cannot be prepared until the year with which it deals is completed. So that the mass of material which Mr. SHIRLEY MURPHY had to sift and to codify could not be in his hands until late in 1903 and it might well take him the rest of that year to deal with it. The result is to place at the disposal of the London County Council a large book containing tables and diagrams involving an immense amount of work in their preparation. We point all this out because the accusation of dilatoriness is easily made, while the advantage of time, by which fulness, accuracy, and clearness are secured, is not so generally perceived.

We shall, as usual, deal with the report in a short series of articles drawing attention to the prominent lessons contained in it. For the public health of London may be looked upon as a type of the public health of any urban community in England, and, indeed, of most urban communities where attempts are made to regulate life in accordance with modern sanitary requirements. We have in London all sorts and conditions of persons to deal with, while types are to be found of every kind of town. The splendidly built houses of the rich standing round open squares, looking out on large parks, and flanking broad streets, are in many districts in contiguity with overcrowded slums, ancient mews, and open-air markets. There is a riverside population with all the squalid environment of a busy port. There is a commercial, an industrial, and an artisan population, and large districts of London are monopolised by one or the other. Stretching into the suburbs the same acute differences obtain. The amenities of life in Hampstead differ as much from those in Haggerston as the standard of luxury in Lambeth varies from that in Grosvenor-square. Every sort of administrative sanitary problem at some time or other during the year is consequently placed before the Public Health Committee of the London County Council to be submitted to its medical officer of health, and in his report Mr. SHIRLEY MURPHY has made piquant uses of such opportunities of contrast. The London death rate from all causes per 1000 living was only 17·2 during 1902, the lowest figure ever recorded except that for 1901, which was 17·1. The factors which contributed to this decrease in death-rate are well shown in the diagrams, and the influence of the decrease in infant mortality will be observed with pleasure. Too much stress, however, cannot be laid upon the better chances that infants apparently enjoyed during the year in question, as the figure for infant mortality is largely dependent upon the prevalence of infantile diarrhœa. When infantile diarrhœa has been rife infant mortality mounts, and it is no exaggeration to say that one of the greatest tasks at the present time before a medical officer of health of any large urban community is the control of infantile diarrhœa. Some interesting observations with regard to the death-rate will be found in Mr. SHIRLEY MURPHY'S comparisons of life expectation in Hampstead and in Southwark, those being the two districts that he has arbitrarily selected to represent the situation of the homes of the well-to-do and that of the homes of the poor. In Hampstead the expectation of life at birth is in the case of males 50·8 years and in the case of females 56·6 years, while in Southwark the corresponding figures are 36·5 and 40·7 years respectively. In the same section of his report—i.e., where comparison is being instituted between the incidence of mortality upon the well-to-do and upon the poor—Mr. SHIRLEY MURPHY interpolates an interesting little quotation from Dr. FARR'S life tables. He finds that taking Hampstead as 100, the comparative expectation of life at birth in Southwark is now 72, while in St. George's Hanover-square in 1841, according to Dr. FARR, the expectation of life was only 74. It would not be fair to deduce from this that the inhabitants of Southwark to-day in every circumstance of occupation and environment are as well off as the inhabitants of St. George's Hanover-square were 60 years ago, but short of this deduction it is obvious that the conditions of life in the poorer districts of the metropolis have enormously improved during the indicated period. The story, in spite of many hitches and in spite of vested abuses, is one of progress.

The year 1902 witnessed, of course, a serious epidemic of small-pox. We do not want to minimise the importance of that epidemic, the risks to the community, or the expenses to which the various boroughs were put, but we cannot refrain from pointing out that in 1902 1314 lives only were lost out of a population of 4,579,110. Mr. SHIRLEY MURPHY'S plan, showing the comparative death-rates for small-pox for the years 1841 to 1902, indicates that in 1902 the deaths from small-pox were relatively few as compared with those which occurred in times of epidemic prevalence of former years We have no doubt whatever that the fact that the death-rate was so low depended on the administrative measures adopted for the limitation of the spread, and was in particular due to the removal of the small-pox hospitals outside London the result of the work of Mr. W. H. POWER, the principal medical officer of the Local Government Board. It is true that in their new situations they acted as centres to some extent for the convection of the disease but the benefit to London has been immense In our subsequent articles we shall have more to say concerning this epidemic and the methods by which it was arrested at the instance of the health authorities.

Annotations.

"Ne quid nimis."

THE LANCET RELIEF FUND.

THE annual report of the almoners of this Fund appears on p. and 178 form a of application for relief under the Fund is included in our present issue, and will be found to be readily detachable for use in case of need. These two documents contain the conditions subject to which distribution of the Fund is made and it will prevent possible disappointment on the part of applicants if they are carefully studied and if the object for which the Fund has been instituted and has been carried on for 15 years is clearly understood: this is the affording of immediate pecuniary help to registered medical practitioners or to their recently bereaved dependents in cases of sudden distress and emergency but not in cases where the need is chronic The value of such aid, when it is both timely and prompt will readily be appreciated and the promptitude with which THE LANCET Relief Fund is made available by the almoners will be judged from the statement that cases are not infrequently considered and assistance is granted on the day on which the application is received. Upon occasions of bereavement where, in addition to the grief inseparable from such calamity there is the crushing sense of helpless poverty, the relief thus afforded may, it is hoped, be of no insignificant order. The report for the year 1903 contains no remarkable features, although in various matters of detail it differs from the one which preceded it. There were in 1903 only three more applications for relief than in 1902, but a much larger proportion of these complied with the conditions laid down, so that gifts of money were alloted in 33 instances as against 24 in the preceding year; one payment voted in 1902 was made, and whereas there were no loans in 1902 four, amounting to £76 14*s.* 6*d.*, were sanctioned in 1903. Beyond this the statement of accounts and report speak for themselves and it is again our privilege to thank those who have aided us in distributing the Fund so as to make it an effective aid to those intimately connected with the medical profession in times of sudden and urgent necessity. The names of those to whom we would thus acknowledge our indebtedness are the same as last year with the exception that Mr. John Tweedy having succeeded Sir Henry G. Howse as President of the Royal College of Surgeons of England has thereby become an almoner and we thank him for having kindly consented to undertake the duties. With him are associated Sir William Selby Church, Bart., K.C.B., President of the Royal College of Physicians of London, and Sir William Turner, K.C.B., President of the General Medical Council; whilst Sir Henry Pitman, for many years Registrar of the Royal College of Physicians of London, is so good as to continue to act as honorary auditor. Again directing the attention of those who may be either seeking or assisting to procure the help offered, we desire to point out that all applications should be made on the prescribed form and addressed to the Secretary of THE LANCET Relief Fund, 423, Strand, London, W.C.

THE PRESERVATION OF ANTIQUITIES FROM FIRE.

IT would appear that an unusual number of fires, to say nothing of the terrible catastrophe at Chicago, have taken place of late. Country mansions, factories, inns, and various other structures attest the ubiquity of the so-called destroying element. In Worcestershire we regret to notice that Sir Edmund Lechmere has suffered another serious loss, his residence at Hanley Castle being destroyed. This gentleman was the owner of "Severn End" in the same county, a historic mansion immortalised by Harrison Ainsworth, which was almost totally destroyed some years ago. This house, which was one of the oldest in the kingdom, not only contained an interesting museum, which was open to inspection by the public, but also what, we believe, was extremely rare, an ancient laboratory where no doubt bygone members of the distinguished family pondered on alchemical problems, the foundations of which modern research seems to be doing something to rehabilitate. It would seem possible that in the quiet of these old country mansions, as in the gloom of the cloister, important discoveries were made which were in advance of the age and consequently not appreciated. The question arises, Can anything be done to stop this destruction by fire? It seems doubtful if the custodians of country mansions are equal to the task allotted to them. We would urge on all who possess the priceless treasures of antiquity to see that the guardians of such have both the mental and bodily qualifications, as well as goodwill, for their important charge.

THE SANITARY INSTITUTE LECTURES.

THE thirty-seventh course of lectures and demonstrations for sanitary officers will begin on Feb. 2nd at the Parkes Museum, Margaret-street, London, W., and will terminate on April 25th. The course is divided into two parts, the first part dealing with elementary physics and chemistry, hygiene, the laws of public health, and other subjects connected with sanitation, while the second part deals with the inspection of meat and the laws relating to the sale of meat and other articles of food. The names of Dr. E. J. Steegman, Dr. J. Priestley, Dr. E. P. Manby, and Dr. Reginald Dudfield are included in the list of lecturers. In connexion with this course a series of demonstrations will take place on successive Saturdays and Wednesdays throughout February, March, and April. On Feb. 6th, for example, there will be an inspection and demonstration at the new buildings of Charing Cross Hospital which will be conducted by Mr. A. S. Snell, F.R.I.B.A., on Feb. 27th Dr. J. F. Butler-Hogan will show to a party of students the working of the Tottenham disinfecting station and the dust destructor, on March 9th Dr. J. King Warry will take a small company of students through the district of Hackney for the purpose of inspecting the sanitary arrangements of that borough, and on April 27th Mr. J. King, M.R.C.V.S., will conduct an inspection and demonstration at the Metropolitan Cattle Market. Demonstrations on the sanitary apparatus and appliances in the Parkes Museum will be given from time to time by Mr. A. W. Harris and Mr. E. W. Wallis, F.S.S. The fee for the complete course is three guineas. The fifth course of practical training for meat inspectors will begin on Feb. 26th. This course, which lasts for two months, includes practical training at a cattle market. The fee is £3 13*s.* 6*d.*

ON THE KATATONIC FORM OF ADOLESCENT INSANITY.

THE adolescent forms of dementia have received much attention during the past few years, especially as regards their bacteriology and treatment. Dr. Lewis C. Bruce, medical superintendent, and Dr. A. S. M. Peebles, assistant medical officer, of the Perth Asylum, Scotland, have published in the *Journal of Mental Science* for October, 1903, a series of observations on the katatonic form of adolescent insanity which include certain new clinical and pathological facts of interest. 12 cases of the disease—ten females and two males—were investigated as regards physical symptoms, conditions of the blood, and the presence of bacteria in the blood or tissues. The history of the cases conformed to the classical descriptions of Kahlbaum and Kraepelin as given in the text-books. Nine men and one woman were in the period of adolescence, one woman was over 30 and one man over 40 years of age, "yet the disease was absolutely typical in both." Among the physical symptoms it was noted that the alimentary canal was disordered in every case, there was no desire for food, and vomiting after a meal was very common. The cardiac action was rapid, irregular, and intermittent The above symptoms occurred in the acute stage of development of the disease and were succeeded by the characteristic phenomena of the next or katatonic stage. In no case under observation did the acute stage last longer than four weeks. The katatonic stage was ushered in by a distinct febrile attack in 50 per cent. of the cases, or in default of the febrile attack a high degree of leucocytosis was developed. The alimentary and circulatory systems continued to show the same physical disorders as before and the extremities now grew cold, cyanotic, and œdematous. The temperature was uniformly subnormal and patients in this stage were particularly "liable to tubercular infection." The mental state was one of stupor complicated with delusions of a persecutory nature. Occasional impulsive actions, stubborn mutism, rhythmical movements, and a condition of muscular hypertonicity with resistance to induced movements constituted the symptoms of this stage. Examination of the blood showed that immediately upon the onset of the stupor the leucocytes fell to below 8000 per cubic millimetre but soon rose again to between 12,000 and 16,000 and the percentage of polymorphonuclear cells fell to about 60. As recovery set in the percentage of the latter increased. Bacteriological examination of the blood was made in eight cases. Three of these gave positive results and from one of the three cases a pure culture of a streptococcus was obtained which agglutinated in the serum of patients suffering from katatonia. "We have tested," add Dr. Bruce and Dr. Peebles, "the agglutinative power of the blood of 50 other patients, not cases of katatonia, to this streptococcus and only five gave the agglutinative reaction." It is probable, therefore, that a specific agglutinin is present in the blood of patients suffering from katatonia. Experimental observations were then made on rabbits with cultures of this organism. By infecting rabbits through the alimentary tract or blood stream with the streptococcus a condition of malaise with irregular temperature, increased skin reflexes, and mental hebetude was induced. This disease tended to terminate naturally in rabbits in about six weeks when a condition of immunity was established to this organism. The treatment of katatonia Dr. Bruce and Dr. Peebles consider to be entirely unsatisfactory. All but one of the cases treated by rest in bed, fluid diet, and saline purgatives "ran through the various stages of the disease unchecked." Attempts to procure a serum for the treatment of the disease were made by immunising a goat to the streptococcus obtained from an acute case of katatonia. The serum of this goat was used to treat two patients in a condition of stupor, by subcutaneous injections of 12 cubic centimetres daily. Two other stuporous cases were treated with ten cubic centimetre doses daily and five other cases were treated with subcutaneous injections of sterilised broth cultures of the organism. The object in these serum or broth injections was rapidly to raise the active immunity of the patients. The serum obtained from the goat gave no beneficial results and the active immunisation of the patients in the stuporous stage produced no curative effect. Dr. Bruce and Dr. Peebles conclude that though katatonic dementia is characterised by an acute toxic condition of definite onset and course, accompanied by definite changes in the blood and attended by a condition of mental confusion with stupor and katatonic rigidity of the muscles, the disease tends to run its course unchecked by ordinary medicinal or special serum treatment and that further investigation is needed for the discovery of an effective "anti-serum" for its treatment.

THE REBUILDING OF ST. BARTHOLOMEW'S HOSPITAL.

ON Jan. 7th the deputation from St. Bartholomew's Hospital to the Postmaster-General was received by that Minister and on the same day a court of governors was sitting at the hospital. The deputation returned to the hospital before the court rose and were enabled to lay before its members the following results of the interview. Lord Stanley did not hold out any hope that the hospital would be enabled to buy any of the site of Christ's Hospital from the Post Office, for that department requires it all for itself. But the Post Office has met St. Bartholomew's Hospital in a most friendly manner. The Post Office authorities are going to make a private road 40 feet in width which will only be used by their own vans between their new buildings and those of the hospital. Further, they have instructed their architect to confer with the architect of the hospital as to the best arrangement of the new Post Office buildings so as to avoid taking away more light and air from the hospital than is unavoidable. These facts show a generous and sensible spirit on the part of the Post Office which is highly commendable. Furthermore, the governors of the hospital and the medical staff are in absolute accord as regards the necessity of more land being acquired and, the remainder of the Christ's Hospital site being now impossible to obtain, it has been decided to remove the nurses' home from its present position to some site outside the precincts of the hospital. This will free an area of nearly one and a half acres which, together with the site already purchased from Christ's Hospital, will give about an additional three acres of land to that on which the hospital already stands. There will thus be ample room for the construction of a thoroughly well-appointed building and it only remains now to raise the necessary funds; but if a properly thought-out and practical scheme is submitted to the citizens of London at the coming Mansion House meeting we are sure that the money will be forthcoming.

WALLS AND VENTILATION.

THE impression is quite common that in order to secure the efficient ventilation of the house the doors and windows or some aperture connecting the outside air with that inside must necessarily be open. In some cases this is no doubt to a large extent true. It is probably true, for example, in the case of a house situated in the middle of a terrace and in a measure for the semi-detached house. Recourse also to opening the window or ventilators is probably the only means of securing a change of air in the rooms of houses which are externally heavily painted or stuccoed or in which the walls of the rooms are solid or thick or covered with impervious paint or paper. The fact is that considerable ventilation is capable of taking place and quite a large exchange of fresh for bad air is effected through the walls of buildings. Many a room that is notoriously "stuffy" could doubtless be made pleasant to live in by removing the solid paper or impervious coat of paint from the wall and substituting porous paper or, better still, giving up paper altogether and using a distemper wash of pleasing tone. It is not appreciated as it ought to be that the common brick wall and plaster permit of considerable ventilation. The man who would live in fresh air when not out of doors and who objects to the open window would therefore accomplish the consummation of his wishes by choosing a detached house or as next best to that a semi-detached house or one at either end of a terrace and seeing that the walls, whether inside or out, had not their porosity interfered with by paint or air-tight paper. Naturally he would avoid the house in the middle of a terrace over the side walls of which he would have no control.

PATHOLOGICAL RESEARCHES FROM THE LABORATORY OF THE LUNACY DEPARTMENT, NEW SOUTH WALES.

THE pathological laboratory of the Lunacy Department of New South Wales was opened in 1900 and Dr. J. F. Flashman of the University of Sydney was appointed pathological director. Accommodation for the building was provided in the University, the laboratory being modelled on the lines of the pathological laboratory established at Claybury Asylum by the London County Council in 1895. Like the latter, says Dr. Flashman, the aim of the laboratory at Sydney is purely scientific, "being the investigation of the changes in the brain and nervous system caused by mental disease." The present volume of reports from the laboratory is the first of its kind issued and contains papers of pathological and neurological interest. The first contribution, by Dr. Flashman, describes the features of the brain of a microcephalic Australian idiot showing the rare absence of a corpus callosum. The brain was that of a patient, aged 17 years. Among the anatomical abnormalities were the presence of convolutions passing across the great longitudinal fissure, the apparent absence of a corpus callosum, and the marked extent to which the cerebellum and insula were uncovered. The hippocampal gyri were extremely broad, a condition characteristic of microcephalic idiocy, as Professor D. J. Cunningham had pointed out some years ago. The second paper, by Dr. Flashman, deals with the parieto-occipital fissure in the brain of four Australian aborigines and points out certain rudimentary features in the same which indicate a stage of evolution less advanced than that of the European brain. This paper is of special interest to neurologists and anatomists. Dr. Flashman in another paper gives a detailed account of all the fissures and sulci of these brains, illustrated with reproductions of photographs and sections. The concluding paper in the volume is by Dr. O Quaife and deals with certain technical methods for the permanent preservation of specimens of the nervous system prepared by the Golgi method. It contains some useful hints on technique. The whole book is well got up and the printing and illustrations are excellent. The volume reflects credit on those concerned in the management of the pathological laboratory of the Lunacy Department, New South Wales, and gives promise of useful work to follow.

HEAVY RAINFALLS, AGRICULTURAL FAILURE, AND THE NEED OF SCIENTIFIC AID.

ONE consequence of the heavy rainfall of last year should not be overlooked by those who have the welfare of the country at heart. We allude to the impoverishment of the soil owing to the soluble fertilising ingredients, especially those containing nitrogen, being washed away by the repeated downpour. Apparently there is an impression that the saturation of the earth during the last season will, if conditions are otherwise satisfactory, lead to a "bumper" year for the agriculturist. This is a mistake, for useful though a copious supply of moisture may be there must be replacement of the essential manurial ingredients to bring out its full value. The present year is therefore decidedly a year when the farmer should have effective advice as to the condition and treatment of his land. We have already called attention to the parlous state to which analytical chemistry had been brought in Ireland by the old bad system of "cumulative" appointments and we regret that the same cause is working evils in this country. Some ten years ago the Fertilisers Act was passed and was framed for agriculturists much on the lines of the Sale of Food and Drugs Act. Unfortunately this Act has been almost a dead letter, for the "district" agricultural chemist, instead of being actively employed in the country and an available servant to the farmers, shielding them from imposture and benefiting them with advice, is carrying on scientific agriculture shut up in a laboratory in the city. This is the age of "personal service" and the analytical chemist should be in evidence or his sphere of usefulness will be sadly limited The benefits that a resident analytical and agricultural chemist in each county could confer are boundless and the question should form one for discussion by such a body as the Institute of Chemistry.

PREMATURE DISCHARGE OF SCARLET FEVER PATIENTS.

AT a meeting of the Metropolitan Asylums Board held on Saturday, Jan. 9th, a letter was read from the medical officer of health of the Stepney borough council forwarding details of four cases in which a fresh outbreak of scarlet fever had followed the discharge of patients from the Board's hospital. The communication stated that the council had had under consideration a letter from a resident at Shadwell in which he stated that on Nov. 26th one of his children was removed to one of the Board's fever hospitals suffering from scarlet fever and was discharged therefrom on Dec. 18th. On her arrival home there were distinct signs of peeling. The result was that five days afterwards a second daughter was seized with the same disease. Moreover, three other cases of premature discharge with consequent infection of other patients had come before the attention of the public health committee. The council drew attention to the great danger to public health caused by the action of the Board in discharging patients before they had finished peeling, thereby causing unnecessary suffering to patients, great inconvenience to relatives, and a large amount of additional expense to the ratepayers generally. The letter concluded by asking that the cases might be thoroughly investigated and for the Board's observations thereon. It was decided to refer the letter to the hospitals committee for consideration and report.

TWO NEW ROMAN OCULIST SEALS.

AN account of an oculist seal found at Rugles was given in THE LANCET of Sept. 5th, 1903, p. 725. Two more will now be reported upon but the first of them is only known by a careful copy of the inscription made by an antiquary named Garrucci whose note of it has recently been discovered having remained hidden away among sundry papers since 1867. The seal was disinterred at Arles in the Rhone valley and its readings are preserved among the notebooks of the late Dr. Sichel who obtained them from Garrucci. Dr. Sichel devoted a considerable amount of time to the medical side of the evidence afforded by oculist seals and published his results which have been much utilised by scholars in studying new specimens from time to time. This particular signet belonged to an oculist, Lucius Tettius Sabinianus, and bore the following inscription, omitting the fourfold repetition of his name :—

"L(ucii) Tetti(i) Sabinia(ni) authem(erum) ad lipp(itudinem)
diac(h)yl(um) ad cal(iginem)
.... ad lippi(tudinem)
... diachol(es) ad dia(theses)."

The translation of the inscription is as follows :—

"(Collyrium) authemerum of Lucius Tettius Sabinianus against ophthalmia.
(Collyrium) of sugar of plants ...... against obscurities of vision.
Collyrium . ... against ophthalmia.
Collyrium of gall against diatheses."

The first remedy appears to have been identical with another collyrium mentioned by ancient medical authors but not yet found upon oculist seals, known as "monohemera." The special characteristic of "authemerum" and "monohemera" was rapidity of action, for they were reputed to effect a cure, or considerable amelioration of the symptoms, within a single day. Several formulæ for authemerum are given by ancient writers such as Paulus Ægineta.[1] The collyrium diachylum mentioned next in order conveys its own meaning: it was a vegetable sugar and has only once before been found upon a seal and then without any addition to show the purpose for which it was recommended. Ætius, however, twice speaks of it. Scribonius used it for "caligo," or defective vision. The seal of Gaius Valerius Amandus found at the "Ballast Hole," near Biggleswade, and now in the British Museum, mentions caligo, giving stactum as its remedy—that is, oil of myrrh. The third line of this seal does not require comment. Diacholes in the fourth had gall (διαχολῆς) for its base. It was used to cure leucoma and ulcerations of the cornea. All that can be said about it is told by M. Villefosse and M. Thedenat in their "Cachets d'Oculistes Romains." The second seal is of importance because its inscription is in Greek, it being the third, or perhaps the fourth, yet known. It reads :—

---

[1] De Re Medicâ, iii., 22.

Δικεντη(τον) = dicentetum.
Κυκν(αριον) = cycnarium.
Χλωρον = chloron.

It was discovered in a lady's tomb by Dr. Sauvage when excavating a Merovingian cemetery at Boulogne. Dicentetum was treated of in the notes upon the Rugles seal published in The Lancet of Sept. 5th. It means "of special power," or strength. Ætius gives its ingredients as misy, sugar of poppies, verdigris, and gum. Cycnarium occurs in Galen and in Paulus Ægineta ;[2] it meant "swan-coloured" (κύκνειὸς)—i.e , white. Chloron (χλωρὸς) was green ; it occurs on the seal of Ariovistus found at Colchester.[3]

THE ASSOCIATION OF CERTIFYING FACTORY SURGEONS AND THE VENTILATION OF FACTORIES AND WORKSHOPS.

At the annual meeting of the Association of Certifying Factory Surgeons held in May last year it was decided to ask a special committee of the association to report on the recommendations made in the first report of the departmental committee appointed to inquire into the ventilation of factories and workshops which was issued on August 15th, 1902. This report was dealt with in The Lancet of Feb. 14th, 1903, p. 463. In regard to the recommendations, which are given *in extenso*, we stated that the first, which referred to limitations as to the permissible amount of carbonic acid gas in the air, "is open to very grave objection," while we remarked that "the last two are devoted to recommending the general use of Dr. Haldane's apparatus." These points have now been dealt with by the special committee appointed by the Association of Certifying Factory Surgeons. In regard to the sufficiency of a carbonic acid standard in all cases, the committee points out that it does not follow necessarily that if the proportion of carbon dioxide is found to be below the limit the place is properly ventilated. To quote one example, it is no uncommon practice to have the entrance to a workplace protected by a closed door and it is only on the business of the factory inspector being known or made known to the janitor behind the wicket that the desired entrance can be obtained. Thus an opportunity is provided for "emergency" ventilation before any samples can be taken. The special committee suggests that the difficulty might be overcome by insisting on proper regard being given to the relationship between ventilation and temperature. Obviously the introduction of fresh air to sweep out impurities just before the inspector's visit would disturb the temperature of the room. It is proposed that two thermometers should be fixed in each room in such places that the degree of variation between them would be a guide to the recent opening of windows. The special committee very seriously questions the utility of any order based upon the standard of 13 volumes of carbonic acid in every 10,000 volumes of air and it quotes a few important arguments against the adoption of too low a standard of purity which we, think, are very much to the point. It agrees that the standard should be lowered when gas or oil is burning, though not to the extent—namely, 21 parts per 10,000—recommended by the departmental committee. It is suggested that a reasonable proportion of carbon dioxide over and above that of the outside air which might be allowed during gaslight would be double the amount allowed in excess of outside air during daylight. In any case the committee thinks, and we agree that it is quite sound in principle, that the standard should be stated in terms of carbonic acid in excess of that found in a sample of outside air taken at the same time. It is clearly not reasonable that an employer in the outskirts of the city with better natural facilities for ventilation should be allowed an extra volume of respiratory impurity over and above that conceded to the employer in the town. In the case of Manchester, for example, a difference of one volume of carbonic acid per 10,000 between the atmosphere of Manchester proper and the immediate outskirts exists owing, not to respiratory impurities, but to smoke troubles and stagnant air. The practical utility of the suggestion is doubted of asking inspectors to conduct estimations of the amount of carbonic acid by means of Dr. J. S. Haldane's apparatus which is certainly not simple and would require the attention of an expert There are much simpler methods which are sufficiently accurate for the purpose. The committee concludes that an equivalent of impurity to the extent of an additional five volumes of carbon dioxide per 10,000 in excess of that found outside would be a fair proportion to allow during daylight and that double this amount cou'd reasonably be allowed during gaslight. It is also of opinion that the basis for legal proceedings should be one volume in excess of that named for a daylight sample and two volumes in excess in the case of samples taken during gaslight. It is added that the limit suggested should also be made to apply to cotton-cloth factories. The report is signed by T. F. Young, Thomas Fort, and W. F. Dearden, the honorary secretary of the association.

FACIAL ERYSIPELAS FROM EROSIONS OF THE NASAL SEPTUM.

In the *Boston Medical and Surgical Journal* of Dec. 17th, 1903, Dr. J. W. Farlow calls attention to a source of facial erysipelas which is not generally recognised—erosions of the nasal septum. These may exist without attracting the notice of the patient or the practitioner. He relates the following cases. A woman, aged 75 years, came under observation for occasional spasm of the throat. Nothing was found except an erosion and crust on the right side of the septum nasi. Two months later she was ill, with a temperature of 101° F. and headache. The septum was red and swollen and there was marked erosion on the right side of the septum, on which was pus. The bridge of the nose on the right side was very red, tense, and painful, and the redness was spreading towards the cheek and the eye. The secretion was removed from the nose and antiseptic dressings and powders were used. On the following morning the temperature was 103° and the erysipelas had spread to the other side of the face. The septum was again thoroughly cleansed and the nose was kept free from secretion. On the next morning she was much better. Recovery rapidly followed. The treatment of the nose seemed to have prevented a fatal result. In another case a woman, aged 40 years, had had several severe attacks of facial erysipelas at frequent intervals. There was a marked erosion of the septum which Dr. Farlow treated. On one occasion subsequently the septum became reddened and there was incipient redness of the bridge of the nose as in the former attacks. The nose was thoroughly cleansed and the symptoms disappeared in a short time. During the remaining nine years of life she had no more attacks. In a third case a man, aged 52 years, had a severe attack of facial erysipelas. When Dr. Farlow examined his nose at a later period he found a marked septal erosion with bloody crusts. Subsequently the nose became reddened and the patient feared an attack of erysipelas ; but treatment of the septum seemed to prevent the attack. None of these patients complained of the nose sufficiently to have it examined, yet when they came under Dr. Farlow's care each had a large open sore. At the Massachusetts General Hospital all cases of facial erysipelas going to the department for diseases of the skin are referred to the department for diseases of the nose and throat for examination of the nose. The importance of Dr. Farlow's observations, particularly in recurrent attacks of facial erysipelas, is obvious.

WILLIAM BLAKE.

AT the present moment there is to be seen at the Carfax Gallery in Ryder-street a collection of the works of that very remarkable poet and craftsman William Blake. He was a man who was certainly born out of due time, for his life 1758-1827, coincided with the time when art, except for Turner, Constable, and one or two other landscape painters, was at its very lowest ebb in England at all events and his strange mystical drawings must have been absolutely incomprehensible to the majority of his contemporaries Take, for instance, "The Nativity," where the Divine Child is floating in the air between the Virgin and St. Elizabeth, or "The River of Life" with its swiftly moving figures. Blake's drawing was often defective and he had a habit of making his figures appear to be about ten feet in height, as exemplified in the picture of Christ raising the son of the widow of Nain; his nude figures also are, as a rule, too anatomical, but his feeling for line is wonderful. He could, however, at times produce nude figures of wonderful beauty —witness the picture of the triple Hecate. He had the same faculty for making his figures move as had Botticelli, a point well seen in the picture of the Ascension, where our Lord is rising and two angels are descending. In all his pictures of fire, also, he gives the flicker and ascent of the flames with wonderful fidelity and his angels really are winged creatures and not men or women with bird's wings attached to them. Even when his angels are sitting still they are angelic and show their spiritual qualities, a good instance of which is the drawing of Raphael talking to Adam, where his wings mount up in a beautiful flamboyant ogee, and there is no need here to refer to the angels in the Job illustration of "The morning stars sing together." The borderline between sanity and insanity is so narrow that it is, perhaps, impossible to say whether Blake was sane or not. Imagination when uncontrolled may be said to be insanity and Blake's imagination certainly played him strange tricks. But, mad or not, the man who could write poetry like the song beginning "My silks and fine array," or paint pictures like the "Ascension," has left treasures to posterity.

THE METROPOLITAN ASYLUMS BOARD AND ITS ASSISTANT MEDICAL OFFICERS.

ON Dec. 21st, 1903, the following communication was received from the assistant clerk to the Metropolitan Asylums Board by seven assistant medical officers in the fever service of the Board :—

[illegible]

of this communication.

The seven assistant medical officers who are referred to above have sent a reply to the Asylums Board in which they express their surprise at the communication. They add that all of them have seen at least one year's service and some of them two years' service, that the terms of the advertisement which they answered, and also the form of application which they filled in, left no room to suppose that the engagement could be terminated in such an abrupt manner. Moreover, when they appeared before the selecting subcommittee several of them were asked whether they would be willing to serve for several years and they were only appointed on giving such an assurance. The protestors add that they were elected in an emergency and worked at high pressure and that they did not expect that a lull in the work would be made the opportunity for dismissal. They therefore beg the Board to reconsider its decision. We cannot but think that the Asylums Board has acted harshly in this matter. No one can expect the same staff to be kept up during a time of freedom from infectious disease as during an epidemic, but the Board should not, as it appears to have done, have implied that the term of service of the assistant medical officer would be for several years. A month's notice is far too short a time to give to men who have most of them resigned good permanent appointments to assist the Board in a difficulty (three months at least should have been given), and for a body which has wasted thousands of pounds of the ratepayers' money over the Brook Hospital, to treat its employés with what we must call calculated meanness is not right, to say nothing of the fact that when the next epidemic comes the Board will find it very difficult to obtain the services of extra medical officers. This is a bad policy, for not only does it mean increased mortality but increased expense.

THE medical officer of health of the Cape Colony states that for the week ending Dec. 19th last only 1 case of plague was discovered in the Colony—namely, a native male at East London. Plague-infected rats continue to be found at various places in the Colony, but in the Cape Town and Harbour Board area 422 rats were examined during the week and none was affected with plague. As regards the Mauritius a telegram from the Acting Governor received at the Colonial Office on Jan. 8th states that for the week ending Jan 7th there were 55 cases of plague and 37 deaths from the disease.

THE interests of Dr. J. F. D. Macara, to whose case we referred last week in a leading article on the Scottish Poor-law Medical Service, have been intrusted to the Medical Defence Union We understand that an "interim interdict," to use the Scotch expression, was obtained last week by the Medical Defence Union against the Durness board to prevent the appointment of a successor to Dr. Macara.

DISQUIETING reports having appeared in the press as to an outbreak of yellow fever in Jamaica the governor of that colony has telegraphed to the Colonial Office that since the death of an officer from this disease which he reported on Nov. 18th last no case has occurred and that the state of health in the island is most satisfactory.

AT the next meeting of the Royal Microscopical Society on Wednesday, Jan. 20th, at 8 P.M., Dr. Woodward will deliver his presidential address on the Evolution of Vertebrate Animals in Time. The meeting will be held, as usual, at 20, Hanover-square, London, W.

THE SALE OF FOOD AND DRUGS ACT.—An interesting point of law was raised at Axminster on Jan. 6th with regard to the Sale of Food and Drugs Act. The inspector under the Act visited a shop and wished to purchase some cheese for the purpose of analysis but the proprietor refused to sell it. The solicitor for the shopkeeper contended that as the inspector did not tender payment for the article he asked for there could be no conviction as the Act distinctly provided that the price of the article must be tendered. The inspector stated that when he received the goods he would have been quite willing to tender payment for them but he could not offer payment until the goods were ready to be received. The bench of magistrates eventually dismissed the case, although at first the chairman stated that the majority of the magistrates thought it was not absolutely necessary to tender any payment until the cheese had been received. Notice of appeal was given.

THE LANCET RELIEF FUND.

Almoners.

THIS Fund, which came into operation on the 1st of February, 1889, has for its Almoners the President of the Royal College of Physicians of London (Sir WILLIAM SELBY CHURCH, Bart., K.C.B., M.D. Oxon.), the President of the Royal College of Surgeons of England (Mr. JOHN TWEEDY), the President of the General Medical Council (Sir WILLIAM TURNER, K.C.B., M.B. Lond., F.R.C.S. Eng. and Edin., F.R.S.), Mr. THOMAS WAKLEY, F.R.C.S. Eng., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D. Cantab., F.R.C.P. Lond., as Honorary Auditor.

Scope of the Fund.

FOR the guidance of those seeking assistance and of those desirous of recommending deserving cases, it may be useful to record that THE LANCET Relief Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, which is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners, or to their widows and orphans, in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require. In the case of widows and orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.

Chronic Cases ineligible.

WHEN the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established, and, as a result, the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. As the Almoners still receive applications for assistance for cases which are obviously of a *chronic* character, it is thought advisable to append a statement concerning cases of this nature which appeared in THE LANCET of Feb. 16th, 1889:—

> "We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and exp[illegible] the Fund to those applicants whose cases do not seem to come within the scope of the purpose *for which the Fund has* [illegible] is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—

And who, it may be again pointed out, are likely to be permanently benefited thereby.

FIFTEENTH ANNUAL REPORT of the ALMONERS.

For the year ending December 31, 1903.

IN presenting their Fifteenth Annual Report the Almoners have to record that the balance in hand on Dec. 31st, 1902, was £303 2*s.* 11*d.*, to which, on Jan. 1st, 1903, the Proprietors of THE LANCET added the sum of £300, making a total sum of £603 2*s.* 11*d.* available for grants during the year 1903.

The number of applications for assistance received by the Almoners during the year was 76—a slight increase as compared with those received in the previous year—of which 21 *were so obviously* outside the scope of the Fund that they were rejected by the Secretary by virtue of the discretionary power conferred upon him by the Almoners at their meeting on Jan. 1st, 1890; six were rejected by the Almoners after due consideration; three were withdrawn by the applicants; two were uncompleted at the close of the year; in eight cases Forms were sent but were not returned—probably the applicants recognised that their cases were outside the scope of the Fund; and 36 applicants were relieved by gifts or loans of money ranging from £2 to £35. The relief of the 36 cases, a detailed list of which is given in the accompanying Statement of Accounts, involved the expenditure of the sum of £442 16*s.* 6*d.*—a sum considerably above the normal income of the year, omitting balances brought forward and possible receipts from repayment of loans, and the largest sum voted in any one year since the inauguration of the Fund in 1889.

Letters continue to be received by the Almoners from some of those whom they have helped, expressing their gratitude for the relief which has enabled them to mitigate, and in not a few cases to overcome, their difficulties, and thus testifying to a pleasing feature in the administration of the Fund.

The promptness of the relief afforded to applicants is also a feature to which the Almoners continue to give their particular attention; in this connexion it may not be uninteresting to record again the fact that on several occasions the Almoners have been able to consider cases and to grant relief on the actual day on which the application was received.

There continue to be far too many applications received for assistance for what are *obviously* "chronic" cases, a large proportion of the 21 cases *rejected* by the Secretary coming under this heading. It cannot be too emphatically reiterated that THE LANCET Relief Fund exists to meet cases of *sudden emergency*, where timely help will *tide the* practitioner over unforeseen difficulties, or afford his *widow* and orphans a few weeks' respite from the more pressing financial cares of their unhappy position.

Mr. John Tweedy having succeeded Sir Henry Howse as President of the Royal College of Surgeons of England in July last, thereupon became an Almoner of the Fund and consented to act as such. The present Almoners desire to record their appreciation of Sir Henry Howse's excellent services to the Fund.

In conclusion, the Almoners desire to state that they will at all times be glad to have their attention called to any cases of genuine distress coming within the scope of the Fund, but they trust that those recommending cases or giving testimonials will first take steps to satisfy themselves of the *bona fides* of such cases before endorsing them. In the administration of such a Fund as this the Almoners are of necessity largely guided in their decisions by the testimonials accompanying the applications.

Balance at Bank, Dec. 31, 1903 ...				160	2	3
				£603	2	11

I find by the Bankers' Book that the actual Balance on Jan 1st, 1903, to the credit of the Fund was £303 2*s.* 11*d.*, to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 1st, 1903.

The balance at the Bank on Dec. 31st, 1903, was the sum of £160 2*s.* 3*d.* I have also checked the receipts for disbursements and find the above account strictly accurate.

January 4th, 1904.

HENRY A. PITMAN, Hon. Auditor.

THE INTRODUCTION OF AN AGE LIMIT AT THE ROYAL INFIRMARY, EDINBURGH, FOR THE MEDICAL AND SURGICAL HONORARY STAFF.

(FROM A CORRESPONDENT.)

AT the annual general meeting of the court of contributors of the Royal Infirmary of Edinburgh held on Jan. 4th publicity was given to a matter which up to then might have been regarded as of the nature of confidential relations between the managers on the one hand and the honorary staff on the other. In the report submitted by the managers it was intimated that "the managers had, after most careful consideration, introduced a new rule to the effect that the ordinary physicians and surgeons should retire in future on attaining the age of 65 years. The limit was originally fixed by the board at 60 years, but in deference to the strongly expressed wish of the medical and surgical staff it was afterwards extended to 65 years. It was resolved, however, that the rule should not be applied in the cases of those members of the staff who were at present serving their second or third term of five years in charge of wards nor to the professors. It was at the same time resolved that the charge of wards set apart for the instruction of women students (hitherto held by the senior assistant physician and the senior assistant surgeon) should now be regarded as a full charge and count towards the full term of office as ordinary physician and surgeon." It will be seen that no reason for this change is given—it appears to be quite an arbitrary decision. It is not suggested that physicians or surgeons at the age of 65 years were unfit for hospital work, for were that the contention it would have left the board open to the reply that present seniors, whether professors or not, were continued in office in spite of their incompetence. The history of this sudden new departure is somewhat as follows. So far as can be ascertained it appears that there had been expressions of dissatisfaction on the part of assistant surgeons as to slowness of promotion. Acting apparently on this somewhat vague spirit of discontent the managers without any consultation with the staff intimated that they had determined upon an age limit of 60 years but exempted from it the two sets of persons indicated in the quotation from the report given above. It will be noted that this new regulation was not confined in its application to future appointments but was applicable to present holders of office. The regulation in fact affected nearly the whole of the assistant physicians and surgeons and some of the full staff. It therefore gave rise to much excitement and to much hostile comment. It may here be mentioned that the full physicians and surgeons have charge of wards for three periods of five years each and then retire, and that the assistant physicians and surgeons are promoted to charge of wards in order of seniority on the staff. These assistants are also appointed for periods of five years but they have always been looked upon as having absolute security of tenure and certainty of promotion. Were it not so men would not give up so much of their general practice as they do in order to devote themselves to the duties of the infirmary and of the school of medicine. The new regulation cut into the time during which the junior staff expected to have charge of wards and it was keenly resented. Instead, however, of opposing it as a breach of custom, if not of contract, they decided to fight for an extension of the limit to 65 years and this the managers acceded to. The 65 years limit only fell upon a few assistant physicians, so that the hastening of promotion, which was the avowed motive of the managers for the new regulation, was confined to those appointments and in not one of them does it become operative for something like ten years from now.

This explains the paragraph quoted above from the annual report of the managers to the court of contributors, which seemingly constitutes the final authority in infirmary matters. At this meeting it was proposed "that in the public interest the age limit enacted by the managers of the Royal Infirmary for the ordinary physicians and surgeons be made to apply as well to the physicians and surgeons of the institution nominated by the University." The proposal was submitted by a member of the junior bar who had been evidently coached by someone with a restricted sense of humour, for his whole argument consisted in the assertion that it was the duty of the court to protect the interests of the patients by seeing that they were not attended by physicians and surgeons of the worn-out age of 65 years, and yet he excluded any present physician or surgeon who had reached that age and also excluded the present holders of University nominations. So while the age limit is at once made applicable to certain of the assistant staff, professors may go on to 80 or 100 years, no matter what the loss to patients may be meanwhile. Curiously enough this proposal was opposed by a prominent member of the board of management and by a University representative on the board in the interests of "justice and equity" and "the public interest," and yet so far as is known those gentlemen did not hesitate from any sense of justice and equity to apply their rule to other members of the staff. The motion was carried by a majority of two to one and it is probable that a good many persons wish that the matter of age limit had been left alone and that the managers had instead used the power they possessed of not reappointing men when it became notorious that they were unfit or unsuitable for hospital work and the teaching of students. It is not known what the University may determine to do in the circumstances; the professors hitherto took little or no interest in the question of age limit, seeing that they were specially excluded; now that it has been determined to apply it to their successors it has led to a measure of perturbation. The question has, it seems, to come up before another meeting of contributors to be held shortly.

MEDICINE AND THE LAW.

An Important Decision under the Dentists Act.

MR. FENWICK at Bow-street police-court has delivered a decision of considerable importance in the case of John Panhaus summoned for using a description wrongly implying that he was a person qualified to practise dentistry. The defendant carried on business under the title "Dental Institute (Limited)" and had no registrable qualification. The point was taken on his behalf that as a limited company could not be "a person specially qualified to practise dentistry" there could be no infringement of the Act. The learned magistrate said that it was clear that the defendant was not a qualified and registered person within the meaning of the Dentists Act of 1878. It was also clear that he practised dentistry and apparently he carried on the Dental Institute (Limited) for his sole profit. He agreed that a limited company could not be a person qualified to practise dentistry and he had no doubt that the defendant registered the company for the purpose of evading the Act. The words "Dental Institute" clearly implied that the persons using them were specially qualified to practise dentistry and the defendant must pay fines and costs amounting to £14 1s. This case would constitute an excellent one wherewith to test and to establish the law with regard to the inference to be drawn from such words as "Dental Institute (Limited)" and the liability of unqualified persons practising as medical men or as dentists under such shelter as the title of company may afford. In these circumstances it is better not to discuss previous decisions bearing upon the subject but to wait and to see whether Mr. Panhaus cares to take his case up to the Divisional Court. The findings of fact against him are clearly the only ones which the evidence justified.

Unqualified Practice by a Ticket-of-Leave Man.

James Charles Ady, a coloured man, was convicted and fined £20 with £10 10s. costs at the West London police-court for the use of titles implying qualification to practise medicine in the following circumstances. Ady's name was struck off the Medical Register for infamous conduct in 1896 and in 1898 he was sentenced to seven years' penal servitude for performing an illegal operation. Having been released on ticket-of-leave in April, 1903, he had lost no time in fitting up a surgery in Wardo avenue, Fulham, placing in the window a card bearing the inscription "Institute of Eclectic Medicine—Medical Superintendent, Dr. Ady, L.R.C.P., L.R.C.S. Edin., ex-Med. Reg.," the last three syllables being in smaller type than the rest. It was contended for the defence that these constituted a sufficient notice to the public that the defendant was not a qualified practitioner. In addition two brass plates contained the letters indicating the qualifications under which he had been registered and it was proved that he appended them to his signature. When a clerk in the employment of the solicitors to the Medical Defence Union complained to him of a cough and suggested that he would like "to have a rest and declare on the club," Ady gave the following certificate: "I certify that Mr. Tyrell is suffering from a bad attack of influenza and a few days' rest would greatly aid in his recovery.—(Signed) James O. Ady, L R C.P., L.R C S. Edin., 1878."

Professional Secrecy in America.

Medical practitioners in this country have often appealed against the principle of English law which imposes upon them in certain infrequent circumstances the duty of divulging in the witness box the professional confidences of their patients. The courts of this country do not recognise the right on the part of a medical man to refuse to give a patient's name or to state the nature of the disease from which that patient is suffering. But when practitioners are very much averse from making the disclosures required of them they always find judge, jury, and all counsel concerned anxious to spare them. In one case which was heard in Scotland in 1896 a medical man who brought an action against an insurance company on an accident policy allowed judgment to go against him rather than disclose the name of the patient from whom he had caught the infection.

In America, however, the legislatures of some of the States have adopted the principle of excusing the practitioner from having to make disclosures. Thus by the New York Civil Code :—

> A licensed physician or surgeon cannot without the consent of his patient be examined in a civil action as to any information acquired in attending the patient which was necessary to enable him to prescribe for the patient.

A similar enactment is in force in many other States, subject, however, in some cases to the further provision that ie consent may be given by the legal representative of a eceased patient. It might be thought, and so far as embers of the medical profession are concerned it is ndoubtedly the fact, that this enactment works well in ractice. A reference, however, to some of the cases which ave recently been decided in the American courts shows that ircumstances arise which make its practical application omewhat difficult for the patient.

In the first place, the American courts in applying the ule seem to draw a distinction between civil and criminal ases. When the defendant, who was charged with rape, as examined while in gaol by physicians who were not ummoned by him, and against his consent, their testimony nat they [illegible] ase which was al [illegible] from the risoner, [illegible] not come ithin the meaning of the phras [illegible] ion by a patient to his physician [illegible] 35). The rule seems to be differ [illegible] n Pennsylvania an action was brought by a person to ecover damages for personal injuries sustained in a railway ccident Under a statute there in force a physician could ot, without the consent of his patient, be examined n a civil action as to any information acquired in attending a patient which was necessary to enable him to prescribe or the patient. The railway company sent a physician o examine the injured man on their behalf. It was held that he was not entitled to testify, it being apparently presumed by the court *in such* a case that the relation of physician and patient existed during such examination and that the information obtained was for the purpose of enabling the physician to prescribe and to act for the patient. This [illegible] y to lead to grave [illegible] No doubt if the [illegible] rpose to allow the [illegible] estigations in the consulting room he will consent to waive the privilege, but if in the reverse case he is able to withhold his consent grave [illegible] Vaiver may arise by implication of law. [illegible] waiver of privilege if a witness states what her physician has said as to her [illegible] Missouri Pacific Ry. Co , 93 Mo. App. 219). But it is the patient or his personal representative only who can grant the waiver. Thus the Code of Civil Procedure of the State of New York, Section 83, provides that a physician shall not be allowed to disclose any information acquired in attending a patient in his professional capacity which was necessary to enable him to act in that capacity, and Section 836 provides that a physician may disclose the mental or physical condition of a deceased patient when the provisions of the previous section have been expressly waived by the personal representative of the deceased. It was decided in an action by a widow against a mutual benefit insurance company that the testimony of her husband's physician, introduced in her behalf, that the husband was in a state of delirium prior to his death by suicide, was improperly admitted, the widow not being the executrix or administratrix of the husband and therefore not competent to waive the provisions of the section. This case merely requires to be stated to show that the law of which it purports to be an interpretation is both harsh and unjust. Suppose in America an action was brought by a widow to recover damages for the death of her husband alleged to be caused by the negligence of the defendant. Suppose, further, that the whole question in the case was whether the death of the deceased had been caused by that negligence. Unless the widow was the personal representative of the deceased and as such able to permit her husband's medical attendant to give evidence she would be unable to recover. Hard cases of this kind seem to show that the law as applied in the United States is misconceived. The whole object of making secret the confidences of the consulting room is to protect the patient, not to injure him or those dependent on him. We have already seen that in a civil action the defendant may find it hard to adduce medical testimony. The following case is a further illustration of this Under a statute providing that a physician should be incompetent to testify except with the consent of his patient as to any knowledge acquired by him in treating such patient, the defendant in an action for malpractice was held not entitled to compel the plaintiff to testify that another physician had taken an x-ray photograph or skiagraph of her injured knee, which he had done for the purpose of treatment (Aspy *v.* Botkins, 66 N.E. 462).

THE MIDWIVES ACT, 1902, AND IRISH TRAINING INSTITUTIONS.

CERTAIN conditions imposed by the regulations of the Central Midwives Board upon candidates for examination with a view to enrolment upon the Midwives Register are likely to act with considerable hardship in the case of Irish institutions justly held in high esteem as training schools in midwifery unless the Central Midwives Board can see its way to modify or to supplement its rules with a view to meet the difficulty which has been pointed out. The Central Midwives Board has laid down that the candidate for registration as a midwife before presenting herself for examination must have attended and personally delivered 20 cases of labour and that she must have nursed 20 such cases for ten days after confinement. At a recent meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland the President, Dr. A. J Smith, stated that it would be impossible for such institutions as the Rotunda Lying-in Hospital, the Coombe Lying-in Hospital, and the National Lying-in Hospital in Holles street, Dublin, t[illegible] conduction, as to do [illegible] of the hospitals, and [illegible] nurses in the Dublin hospitals to nurse their patients for ten days after delivery because the practice is for patients to leave at the end of the eighth day and that if this time were to be extended by the hospitals there was no likelihood that the majority of their patients would remain longer. In these circumstances those present at the meeting unanimously passed the following motion :—

[illegible]

A further motion was also submitted to the meeting and passed unanimously to the effect that the Midwives Act should be extended to Ireland. At present it extends neither to Ireland nor to Scotland and it is with regard to midwives likely to be trained in Ireland for practice as midwives in England that the difficulty indicated has arisen. It must not be forgotten in considering it that Section 2 of the Midwives Act provides that "any woman who within two years from the date of this Act coming into operation claims to be certified under this Act shall be so certified provided she holds a certificate in midwifery from the Royal College of Physicians of Ireland or from the Obstetrical Society of London or the Coombe Lying-in Hospital and Guinness's Dispensary or the Rotunda Hospital for the Relief of the Poor Lying-in Women of Dublin, or such other certificate as may be approved by the Central Midwives Board, or produces evidence satisfactory to the Board that at the passing of the Act she had been for at least one year in *bonâ fide* practice as a midwife and that she bears a good character."

The result of this is that although under the Act itself women trained in the institutions named are, during the time specified, entitled to be enrolled without further question as to the sufficiency of their training, in the following year and afterwards, under the rules framed by the Board, they will not even be deemed to be qualified to present themselves for examination. The training afforded to women by the midwifery institutions in Ireland which are named in the section quoted is highly and justly esteemed by all who are acquainted with the subject. The case on their behalf, and in support of the views of those who would regard the training afforded by them as a sufficient preliminary practical education for the purposes of the Midwives Act, was thus forcibly put by Dr. Henry Jellett in a letter to Dr. W. Japp Sinclair, a member of the Central Midwives Board, which Dr. Jellett read at the meeting referred to and to which he had received a reply recognising that the Irish hospitals had a substantial grievance. Dr. Jellett inquired of Dr. Sinclair what would be the position of the Irish nurse who applied to be admitted to the examination of the Board and said, "I have been a pupil midwife for six months at one of the Dublin incorporated hospitals. During that time I have attended a regular course of instruction, I have watched some 300 or 400 deliveries, I have personally assisted at some 20 to 30, I have personally conducted some three or four, I have watched some 600 to 800 women during their puerperium, and I have personally nursed some 20 to 30. I have passed the examination of the hospital." There is a great deal of force in the argument that is thus suggested. The Central Midwives Board had to frame rules in order to secure the practical efficiency of women presenting themselves for examination and to provide a test. It had a perfect right to make its standard of efficiency a high one and to lay down a test which would maintain that standard in all cases. The question at issue relates to the test imposed. If that test admits only women whose practical training is superior to that afforded by the Dublin hospitals and excludes women trained in those institutions with others who in point of efficiency do not come up to the Board's requirements it carries out conditions which the Board has a right in its discretion to impose. If, on the contrary, all women trained in the Dublin incorporated hospitals are excluded by a hard-and-fast rule which at the same time admits to examination women whose practical training is inferior to theirs it cannot be said that the test is fair and reasonable or that it is one calculated to promote the object for which it was devised. The value of personal experience on the part of the candidate for examination is not to be underrated, nor, on the other hand, is the training in midwifery obtainable in the Dublin institutions the position of which was fully recognised by those who framed the Midwives Act. No one questions the high qualifications possessed by the Central Midwives Board to carry out its difficult duties or its desire to do so in the best possible manner without fear or favour. It was not, however, to be expected that a first set of regulations framed under a new Act of such a nature would meet all the requirements of all conceivable cases and there is no obvious reason why supplementary regulations to settle questions arising from time to time should not be framed when needed and approved by the Privy Council. Until April 1st, 1905, qualified women desiring to be midwives can be enrolled as such under the section quoted above and there is time for the Central Midwives Board and the Dublin hospitals to meet one another's views before any hardship can arise affecting the latter and those seeking their training in them.

Looking Back.

FROM

THE LANCET, *SATURDAY,* JAN. 14, 1828.

By far the most popular classification of diseases at present is that adopted by Dr. Cullen, in his work entitled, "Nosologia Methodica;" a work evincing great genius as well as deep research, and which, although objectionable in its principle, as I shall endeavour to show you, is, nevertheless, highly deserving of your attention, from the great mass of historical information it contains. Dr. Cullen's arrangement is founded principally upon the external characters, or obvious appearances, of diseases, a method borrowed chiefly from the writers on natural history, and which was adopted by Linnæus, Sauvages, and others, but which Dr. Cullen greatly extended and improved. An objection to this plan is, that the symptoms of diseases are often so numerous, as well as various, as to make it difficult to bring them within the compass of a definition, or to distinguish easily between such as are essential and those which are accidental merely; and what are only signs or symptoms are often considered as actual diseases, which, in this way, are multiplied to an extreme and unnecessary degree. Thus he makes above a hundred and fifty different *genera* of diseases, many of which are again divided into *species*, terms that imply differences that are radical and essential, to say nothing of *varieties* out of number. The distinctions proper in *natural history* have, however, very little application to the science of medicine; for diseases are, in fact, seldom more than varieties, deviations merely from the natural state; they are not distinct essences, as in the case with *species* in *natural history*. In this respect diseases may be compared with those changes that are induced on plants or animals by culture, climate, &c, and which are so various as almost to defy methodical arrangement. Diseases, fortunately for you, gentlemen, are far less numerous than this system supposes; indeed, were it otherwise—were all the diseases that have different names here assigned to them, essentially different in their nature, the study of physic would be absolutely interminable. The truth is, that the essential differences between diseases are few, whether we regard them theoretically or practically; they are many in name but few in nature; they differ more in their seat than in their nature, according to the observation of Hippocrates, who says, "Omnium morborum, unus et idem modus est; locus vero ipse, differentiam facit."[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9390 births and 5968 deaths were registered during the week ending Jan. 9th. The annual rate of mortality in these towns, which had been 17·8, 15·4, and 20·6 per 1000 in the three preceding weeks, declined again last week to 20·4 per 1000. In London the death-rate was 19·4 per 1000, while it averaged 20·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7·9 in Barrow-in-Furness, 10·5 in Bournemouth, 11·8 in Hastings, 12·0 in Smethwick, 12·8 in Handsworth, and 13·1 in Walthamstow and in Burton-on-Trent; the highest rates were 24·1 in Salford, 24·6 in Manchester, 24·7 in Stockport, 25·6 in Brighton, 26·1 in Gateshead, 26·7 in Liverpool, 28·5 in Bury, 34·6 in Wallasey, 40·1 in Merthyr Tydfil, and 41·7 in Preston. The 5968 deaths from all causes in the large towns last week included 462 which were referred to the principal infectious diseases, against 423, 369, and 495 in the three preceding weeks; of these 462 deaths 132 resulted from measles, 121 from whooping-cough, 66 from diarrhœa, 60 from diphtheria, 42 from "fever" (principally enteric), 36 from scarlet fever, and five from small-pox. No death from any of these diseases was recorded last week in Walthamstow, Hastings, Southampton, Hanley, Burton-on-Trent, Walsall, Burnley, Kings Norton, Smethwick, Grimsby, Wallasey, Huddersfield, and Stockton-on-Tees; among the other towns hey caused the highest death-rates in Willesden, Bury, Preston, Rotherham, West Hartlepool, *Gateshead*, Newport Mon.), Rhondda, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Willesden, Bury, Blackburn, Preston, Rotherham, and West Hartlepool; from scarlet fever in Bootle; from diphtheria in East Ham, Northampton, Plymouth, and Bury; from whooping-cough n Leyton, Devonport, Aston Manor, Liverpool, Warrington, Rochdale, West Hartlepool, Gateshead, and Rhondda; and from diarrhœa in Merthyr Tydfil. The mortality from "fever" showed no marked excess in any of the large towns. One fatal case of small-pox was registered in each of the following towns: Warrington, Halifax, York, Sunderland, and Gateshead; no death from this disease occurred in any other of the large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 26, 27, and 26 on the three preceding Saturdays, was again 26 on Saturday, Jan. 9th; six new cases were admitted during the week, against six, seven, and four in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 1659, against 1655, 1617, and 1632 at the end of the three preceding weeks; 201 new cases were admitted during the week, against 188, 142, and 194 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 344, 271, and 404 *in the three preceding weeks, further rose* last week to 433, and were 77 in excess of the number in the corresponding period of last year. The causes of 93, or 1·6 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Salford, Leeds, Newcastle-on-Tyne, and in 40 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Kings Norton, Aston Manor, Liverpool, Manchester, Sunderland, South Shields, Gateshead, and Tynemouth.

---

[1] Extract from Lecture No. IX. on the Theory and Practice of Physic by Dr. Clutterbuck at the Theatre, General Dispensary, Aldersgate Street.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20·9, 20·8, and 21·7 per 1000 in the three preceding weeks, further rose to 23·2 per 1000 during the week ending Jan. 9th, and was 2 8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 17 5 in Leith and 19·9 in Paisley, to 24 8 in Glasgow and 46·2 in Perth. The 768 deaths registered in these towns included 15 which were referred to whooping-cough, 15 to diarrhœa, 13 to measles, three to small pox, three to diphtheria, three to "fever," and one to scarlet fever. In all, 53 deaths resulted from these principal infectious diseases last week, against 61, 73, and 71 in the three preceding weeks. These 53 deaths were equal to an annual rate of 1·6 per 1000, which corresponded with the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been nine, 16, and 14 in the three preceding weeks, rose again last week to 15, of which four occurred in Aberdeen, three in Glasgow, three in Dundee, two in Paisley, and two in Leith. The deaths from diarrhœa, which had been 10, 16, and 21 in the three preceding weeks, declined again to 15 last week, and included ten in Glasgow, and two in Aberdeen. The fatal cases of measles, which had been 33, 25, and 26 in the three preceding weeks, declined again last week to 13, of which 12 were registered in Glasgow. *The deaths* from small pox, which had been two, four, and five in the three preceding weeks, declined again to three last week, and all occurred in Glasgow. The fatal cases of diphtheria, which had been three, four, and one in the three preceding weeks, rose again last week to three, of which two were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 184, 180, and 177 in the three preceding weeks, rose again last week to 213, and were 1 in excess of the number in the corresponding period of last year. The causes of 30, or nearly 4 per cent, of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25 6, 19 9, and 1·8 per 1000 in the three preceding weeks, declined again to 27·8 per 1000 during the week ending Jan. 9th. During the past four weeks the death-rate has averaged *26 3* per 1000, the rates during the same period being 17 7 in London and 18·9 in Edinburgh. The 202 deaths of persons belonging to Dublin, registered during the week under notice, showed a decline of 29 from the number in the preceding week, and included 23 which were referred to the principal infectious diseases, against 10, seven, and 16 in the three preceding weeks; of these, nine resulted from whooping-cough, five from "fever," three from scarlet fever, three from diarrhœa, two from measles, and one from diphtheria. These 23 deaths were equal to an annual rate of 3·2 per 1000, the death-rates last week from the same diseases being 1·5 in London and 0·3 in Edinburgh. The fatal cases of whooping cough, which had been four, three, and 12 in the three preceding weeks, declined again last week to nine. The deaths from "fever," which had been two in each of the two preceding weeks, increased last week to five. The fatal cases of scarlet fever, which had been one in each of the two preceding weeks, increased to three last week. The 202 deaths in Dublin last week included 32 of children under one year of age and 58 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons were slightly below the respective numbers in the preceding week. Six inquest cases and three deaths from violence were registered, and 59, or more than one-fourth, of the deaths *occurred in public institutions. The causes of nine, or* nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1903.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·4 per 1000 of the population, estimated at 4,613,812 persons in the middle of 1903 The rates in the three preceding months had been 6 5, 6·8, and 6 0 per 1000 respectively. The rates were considerably below the average in Kensington, Fulham, Chelsea, the City of Westminster, Hampstead, and the City of London, while they showed the largest excess in Hackney, Holborn, Bethnal Green, Stepney, Poplar, and Deptford. Small-pox was rather less prevalent during December than in either of the two preceding months; of the 22 cases notified during the month under notice six belonged to the City of Westminster, four to Lambeth, three to Stepney, three to Southwark, and two to Wandsworth. The Metropolitan Asylums hospitals contained 26 small-pox patients at the end of last month, against 21, 42 and 40 at the end of the three preceding months; the weekly admissions averaged four, against five, ten, and eight in the three preceding months. The prevalence of scarlet fever showed a slight decline during last month; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Bethnal Green, Stepney, Deptford, Lewisham, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 1849, 1794, and 1738 at the end of the three preceding months, had further declined to 1606 at the end of last month; the weekly admissions averaged 168, against 241, 210, and 184 in the three preceding months. Diphtheria showed a slightly diminished prevalence during *December as compared* with that recorded in the preceding month; this disease was proportionally most prevalent in Hackney, Bethnal Green, Stepney, Poplar, Wandsworth, and Deptford. The Metropolitan Asylums hospitals contained 731 diphtheria patients at the end of last month, against 671, 753, and 763 at the end of the three preceding months. The weekly admissions averaged 104, against 114, 121, and 109 in the three preceding months. The prevalence of enteric fever further decreased last month; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in St. Marylebone, Hampstead, Holborn, Battersea, and Camberwell. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 247, 285, and 286 at the end of the three preceding *months*, had declined to 246 at the end of last month; the weekly admissions averaged 30, against 40, 44, and 45 in the three

LONDON HOSPITALS AND CENTRAL CONTROL.

To the Editors of THE LANCET.

SIRS,—The correspondent signing himself "Hospital Surgeon" takes a somewhat gloomy view of the prospect of the establishment of any central control over the present London hospital system which he aptly describes as "an extraordinary example of misdirected and overlapping energy and of obsolete arrangements." If we seek at one step to obtain a central board "free to reorganise at its pleasure, to suppress, to establish, to remove, and to amalgamate," it is certain that this step will long be postponed. Such an all-powerful board could be nothing else but the State and hospitals that could be treated in such a high-handed manner by a central body would be entirely unrecognisable as our great voluntary medical charities of which, with all their faults, we are most of us justly proud. Is there no intermediate position between chaos and municipalisation? Many who have given close attention to the hospital question in recent years would certainly be inclined to say that some progress has already been made towards securing voluntary control, though probably at the same time they would admit that not much effect has been produced thereby in coördinating medical charity. It is, of course, through the three great collecting funds for the London hospitals that some slight, though definite and increasing, control is gradually being obtained over the bodies to whom their grants are distributed. The object of the present communication to THE LANCET is to urge those of your readers who are members of the committees of King Edward's and the Hospital Sunday and Saturday Funds to consider whether these committees might not by united action gain still further control over the medical charities. The proposed line of such united action would be as follows.

Each of the three funds should appoint delegates in order to form a Metropolitan Voluntary Hospitals Board. The proportionate number of delegates from each committee should be determined by the average annual income of its fund. The board might have powers of coöption and possibly some other public bodies might be granted rights of nomination upon it, but the majority of the board should be composed of actual members of the committees of the three collecting funds. To this board should be intrusted the distribution of a certain proportion, say one-fourth, of the annual income of each fund. The conjoint fund produced by thus "pooling" one-fourth of each of the three funds should be distributed on a special plan which is an essential part of the present proposal. To every hospital previously chosen by the board as worthy of receiving its support there should be given a share of the conjoint fund proportionate to the sum which the hospital's supporters had raised in voluntary contributions to their charity during the preceding year. No hospital should be allowed to participate in the conjoint fund which would not admit to its governing body one or more persons nominated by the board. There is no doubt, I think, that this method of a central body proportionately increasing voluntary local contributions, sometimes called the Australian system, with the principle and efficacy of which we have all been made familiar by Mr. Herring's generosity to the Sunday Fund, would be very popular with the hospitals themselves. Its popularity would, I think, enable the hospitals to put up with the nominated governor who under other conditions would be obnoxious to some committees. It should certainly insure greater enthusiasm in the local collection of funds—an enthusiasm which is likely to wane if the present methods of making grants by these three funds are alone adhered to.

I put this proposal forward at the present time when other proposals for the establishment of central boards are in the air because it seems to me advisable whenever possible to utilise existing agencies instead of introducing new competitors. The three funds each appeal to a separate *clientèle;* each has regard to special and different features of economy and efficiency in making its grants. All are well established, steadily growing, and doing most excellent work. Their power for good would be immensely increased by the formation of a central board to coördinate their work, especially if the formation of such a board enabled them to get into closer touch with the hospitals by means of the nominees of the board upon the governing bodies. The establishment of the board might be expected to increase the incomes of the central funds and to lessen the deficits at the hospitals which it is their chief aim to meet. Am I too optimistic in suggesting to "Hospital Surgeon" that by such concerted action as I have here outlined an effective step would be taken towards removing some of the defects of our want of system without at the same time destroying the great voluntary hospitals which are amongst the most honourable features of this city?

I am, Sirs, yours faithfully,

London, W., Jan. 11th, 1904. LAURISTON E. SHAW.

CARDIAC DROPSY IN MITRAL STENOSIS.

To the Editors of THE LANCET.

SIRS,—I have been struck by the fact that in patients who suffer from mitral stenosis general œdema supervenes at a much later stage in the course of the disease than is the case in mitral regurgitation. Dr. A. E. Sansom[1] writes: "Generally speaking, in cases of mitral stenosis œdema is not nearly so marked a symptom as in the cases of mitral insufficiency. A fugitive and slight œdema occurs in many of them, but general dropsy rarely until the final stages, when the right chambers of the heart have become dilated, and the tricuspid valve incompetent; many patients die before this stage is reached." In the final stages, however, œdema is very commonly present, as has been shown by an analysis of 143 cases of cardiac dropsy in which post-mortem examinations were made, since mitral stenosis was found to be present in 68.[2] Œdema in the last stages of mitral stenosis is a condition which would naturally be expected to be present and it would be surprising if it were not found to occur. My object is to endeavour to account for the absence of general œdema in the earlier stages of the disease. The explanation of the phenomenon is naturally difficult and any opinion of its causation which may be expressed must of necessity be conjectural.

A patient suffering from mitral stenosis has not usually the appearances which are so suggestive of the other forms of cardiac disease. There is not the pale and anxious expression so frequently present in diseases of the aortic valves or the congested appearance of the face and the bluish tint of the lips and ears which are so often seen in mitral regurgitation, but, to quote the words of Sir William H. Broadbent,[3] the face has "a good colour and cheerful expression, the lips perhaps being of too crimson a shade of red." At post-mortem examinations the heart in mitral stenosis is not usually found to be so large or its chambers to be so dilated as in mitral regurgitation. On account of the breaking down of the compensation of the heart the consequent dilatation of the cardiac chambers tends to obscure any previous hypertrophy of their walls. For reasons which will be explained later it seems probable that in mitral stenosis there are a considerable amount of compensatory hypertrophy of the walls of the left auricle and very little dilatation of its chamber. If hypertrophy of the left auricle be the usual result of narrowing of the left auriculo-ventricular orifice then failure of cardiac compensation is not so likely to occur or dropsy to supervene until late in the disease, because, as long as the walls of the left auricle continue to undergo hypertrophy they may have sufficient power to overcome the obstruction to the passage of blood into the left ventricle and may be able to prevent any undue and increased strain being thrown upon the right side of the heart. In support of the view that there are hypertrophy and only slight dilatation of the left auricle in mitral stenosis, Dr. D. W. Samways,[4] on making an analysis of 70 cases from the records of Guy's Hospital for the years 1888–91 inclusive, in which this valvular lesion was found to be present at the post-mortem examinations, ascertained that hypertrophy of the walls of the left auricle was present in 36 of the cases. He divided the cases into two classes: those in which the stenosis was severe (in which the orifice would *only just* admit one finger) and those in which the stenosis was less severe than this. There were 36 cases of the former class and 34 of the latter. In 15 cases of the severe form of stenosis there was hypertrophy of the walls of the left auricle with no dilatation of its cavity, in 11 there was hypertrophy with dilatation, in three dilatation alone was recorded, and in seven there was no note made as to the condition of the left auricle. Hypertrophy, therefore, was found in 26 and dilatation in 14 of the cases. Of these 70 cases, 18 came from the surgical wards and in only one of these was dilatation recorded and in this case was associated with hypertrophy of the walls of the auricle. There is therefore considerable post-mortem evidence that hypertrophy of the walls of the left auricle occurs in this valvular lesion.

[2] *Idem*, p. 683.

[3] Broadbent: International Journal of the Medical Sciences, [illegible], p 57.

[4] Samways: Brit. Med. Jour., November, 1896, p. 1567.

Again, Dr. T. D. Acland[5] says: "In cases of mitral obstruction, in which the auricle might be supposed to have extra active work thrown upon it, hypertrophy is more marked than in simp [illegible] cings of patients suffe [illegible] that the left auricle is [illegible] records show an abnormal magnitude of the elevation caused by the auricular systole. The auricular systole is sometimes so exaggerated as to be sufficiently powerful to thrust the heart forwards against the chest wall, and so to make the cardiac impulse commence before the ventricular systole. When compensation begins to fail the elevation caused by the auricular systole becomes greatly diminished and may even disappear. The evidence therefore is in favour of the view that the walls of the left auricle are usually hypertrophied and that its cavity is not dilated or only to a slight extent. The question which naturally presents itself is, Why does hypertrophy of the walls of the left auricle, with very little dilatation of its chamber, occur in mitral stenosis when in mitral regurgitation there are generally a considerable amount of dilatation and only slight hypertrophy?

In mitral stenosis as the left auriculo-ventricular orifice becomes diminished in size the increased strain is chiefly felt by the left auricle during its own systole, since during its diastole the blood is being drawn through the mitral opening by the suction action of the dilating left ventricle. The time occupied by the auricular systole corresponds to about one-tenth of the whole of the cardiac cycle, although when there is mitral obstruction this period is undoubtedly lengthened. It is only during this short period in each cardiac cycle that there is thrown upon the walls of the left auricle an increased strain, which is caused by the greater force required to drive the blood through the narrowed mitral orifice. In consequence the muscular tissue has time to adapt itself by undergoing hypertrophy, since the extra amount of work it is called upon to perform is only gradually increased and only exists for a short period during each cardiac cycle. In mitral incompetency, on the other hand, some blood is regurgitated during nearly the whole time occupied by the ventricular systole, so that the strain on the left auricle is more suddenly increased and continues over a longer period of the cardiac cycle than is the case in the former condition. This might cause some hypertrophy of the left auricular walls, but it is obvious that the conditions are not nearly so favourable for this protective change to take place as they are in mitral stenosis. The chamber of the left auricle will tend to become dilated as it has to contain the regurgitated blood from the left ventricle as well as that entering from the pulmonary veins. It is necessary in mitral regurgitation for the left auricular chamber to be larger than in health, in order that it may hold the increased amount of blood which is poured into it from these two sources during the ventricular systole. In mitral stenosis he increased strain is thrown on the left auricle during ts systole, whereas in mitral regurgitation it is placed upon t during its diastole, and "it is a generally recognised fact hat a very effective cause in producing dilatation of the avities of the heart is undue distension during diastole, nd that if nutrition is well maintained obstruction during ystole tends rather to cause hypertrophy."[6] The result is hat the walls of the left auricle tend to become hyperrophied in mitral stenosis, whereas in mitral regurgitation he tendency is for the cavity of the auricle to become ilated.

The changes which occur in the right side of the heart ust not be forgotten, since very early in mitral stenosis here is hypertrophy of the right ventricular walls, so that t the end of the ventricular systole the left auricle would probably contain more blood than in health. As a result of this hypertrophy there is some tendency for the left auricle to become distended; but the distension would not be nearly so great as in mitral regurgitation, and the increased strain would quickly be reduced by the diastole of the ventricles. With a hypertrophied condition of the walls of the left auricle there will not be so much strain thrown on the right side of the heart as there would be if the cavity of the left auricle was distended and the power of its contractions was diminished. The smaller the chamber of the left auricle the greater power has its contracting walls to drive the blood onwards. This has been pointed out by Mr. Robert H. Woods[7] who has shown that "the blood pressure inside a contracting cardiac chamber varies inversely as the radius of the chamber," and that "if the increasing thickness of the contracting walls be also taken into consideration the blood pressure must finally increase inversely as the cube of the radius."

From these considerations it would appear that the left auricle is placed in much better circumstances to deal with the impeded flow of blood through the heart in mitral stenosis than it is in mitral regurgitation. The result of this compensatory hypertrophy of the left auricle in mitral stenosis is that the other chambers of the heart do not become so early dilated as in mitral regurgitation, and the cardiac dropsy, which so easily appears in the latter valvular lesion, does not present itself until late in the disease. We may conclude, therefore, that hypertrophy of the walls of the left auricle is the chief factor in maintaining cardiac compensation in mitral stenosis, and that it is only after the auricle has begun to fail, which does not occur until late in the course of the disease, that the right ventricle and auricle dilate and dropsy supervenes.

I am, Sirs, yours faithfully,
JAMES E. H. SAWYER, M.A., M.D. Oxon.,
late house physician at St. Thomas's Hospital and at the
Bethlem Royal Hospital, London.

MALIGNANT GROWTHS AND NORMAL REPRODUCTIVE TISSUES.

To the Editors of THE LANCET.

SIRS,—We were greatly interested to learn from the letter appearing in THE LANCET of Jan. 2nd under the above title that Dr. G. T. Beatson had as long ago as 1896 put forward the view "that the active processes seen in a cancerous tumour are best explained by regarding the epithelium of the part as having taken on the properties and powers of germinal epithelium." Though with our present knowledge the term "germinal epithelium" can hardly be applied to cells which are destined immediately to undergo, or have undergone, a reduction division, to which we have applied the terms "gametogenic" and "gametoid," the former to those occurring normally, the latter to those whose presence is abnormal, it would have been difficult at the time he wrote for Dr. Beatson to have come nearer to the facts since demonstrated by us. There are, however, a few points with regard to our paper to the Royal Society which this letter leads us to believe would be elucidated by a brief explanation.

While there is a vague similarity in many respects between the general idea suggested by Dr. Beatson and those conclusions which we have drawn from our definite cytological investigations of malignant growths, we must state that we differ from him in many important details which space will not at present allow us to discuss. We would, however, draw attention to the following points. The chief conclusion drawn by Dr. Beatson from his clinical observations was, as far as we are able to make out from a careful perusal of his original paper, that the ovaries and testicles exercise "a control in the human body over local proliferations of epithelium" and that "the removal of the tubes and ovaries has an effect upon the local proliferation of epithelium which occurs in carcinoma of the mamma." To these conclusions he was led by his clinical observations of several cases, particularly of one of carcinoma of the breast where he removed the ovaries and tubes of the patient. In this case the carcinoma was apparently cured, Dr. Beatson attributing the cure to the removal of the ovaries. Our observations upon malignant growths have, on the other hand, been entirely microscopical and we have simply described what we have seen and are able to demonstrate. We express no opinion, one way or the other, as to the possible influence of the ovary or testicle upon the production or growth of malignant tumours.

[5] Acland: THE LANCET, July 20th, 1889, p. 103.
[6] Acland: loc. cit.
[7] Woods: Journal of Anatomy and Physiology, vol. xxvi. Quoted from Dr. D. W. Samways, Brit. Med. Jour., January, 1897, p. 808.

We would lay particular stress upon the fact that we have shown that cells which have been for a long time carrying out specialised somatic functions may, under certain conditions, become gametogenic and go through a reduction division. In certain plants this occurs normally. In mammalia certain cells in the genital organs are set apart at some period during the life of the organism to produce sexual germ cells, and in these at the proper time reduction takes place normally. When, however, reduction division takes place in other somatic cells abnormally the growth possesses not only a parasitic character but is also malignant. This reduction division may apparently take place anywhere and in any kind of tissue and the presence of such cells enables us to differentiate between benign and malignant growths. With regard to Dr. Beatson not being sure about our statement as to the exact mode of development of normal gametogenic cells, we would merely point out that the features of this particular metamorphosis are matters of common knowledge among cytologists.—We are, Sirs, yours faithfully,

J. B. FARMER.

SPIRAL FORMATIONS IN RELATION TO WALKING, SWIMMING, AND FLYING.

To the Editors of THE LANCET.

SIRS,—Never have I had the privilege of reading so interesting a study of spiral formations as that contributed by Professor J Bell Pettigrew to THE LANCET of Jan. 2nd. I speak with natural diffidence in the matter, but with the exception of some papers by Dr. George Wherry on similar subjects I can recall no other publications that deal with spirals in the same way, and the honour done me by the mention of my name in your columns leads me to congratulate myself not only on having directed Professor Pettigrew's attention to the publication of a combined form of research which others have lamentably neglected but also on the value to the second edition of "Spirals in Nature and Art" of many new materials thus placed within my reach. How much more I should have appreciated so illuminating an article a little earlier I need scarcely say, and if Professor Pettigrew had only had an opportunity of reading my preliminary notes on this subject in their original form I should have been only too glad to embody in my first edition those corrections which would have so much improved it, especially in the case of the two diagrams, the correct authorship of which I acknowledged last July both in *Nature* and the *Athenæum*.

It is unexpected news both to my readers and myself that "the great interest taken in artificial flight of late years ...... has been heightened by the publication (1903) of a small work" which has special reference to the architecture of an open staircase in Touraine. In that little book, I must repeat, the subject of flight was only a side issue and the name of Professor Pettigrew is mentioned with all the respect it deserves in connexion with the beautiful spiral fibres of the ventricle of the heart. But his article in THE LANCET of Jan. 2nd compels me to inform you that I knew nothing more about him or his researches into flight until last June. This may seem stranger to him than it does to those who have been willing to accept me merely as a modest inquirer into various subjects of general interest which scientific specialists seem far too much inclined to keep to themselves, or to conceal in literature apparently written for a select audience and certainly published on a scale by no means commensurate with its importance.

Professor Pettigrew says, that "in none of Leonardo's manuscripts and in none of his figures is the slightest hint given of his having any knowledge of the spiral movements made by the wings in flight." That anyone of the scientific accuracy of Professor Pettigrew should thus be in a position involving complete knowledge of all Leonardo wrote or drew is a revelation which every lover of art and science will warmly welcome. I have only about 500 photographs, in my own possession, of Leonardo's original MSS. on many various subjects; and I have only seen in many cities of Europe those MSS. hitherto known to be in existence. I recognise with pleasure that Professor Pettigrew must have larger sources on which to base his general statement. Of course, he does not solely depend on the one MS. he quotes. Yet even as to this MS. alone I venture to adhere to my original opinion, basing it on general considerations of the translation of the Italian dialect and of the value of evidence with which I am not wholly unacquainted. Leonardo's ideas of flight may not be those of Professor Pettigrew, yet I must respectfully, but finally, refuse to accept the Professor's conclusions as to Leonardo's omissions.

Professor Pettigrew need be under no apprehension that either his own scientific reputation or that of England in the nineteenth century will be lessened by my remarks on Leonardo's manuscripts. He does me too much honour. It seems scarcely likely, to take a parallel instance, that anyone will think less of Lyell if I point out that Leonardo calculated a period of 200,000 years for the accumulations at the mouth of the Po and explained the meaning of the strata in the Apennines revealed by the cutting of the river Lamona. English scholars have naturally made a great advance on the investigations of Leonardo in botany, hydraulics, anatomy, morphology, astronomy, optics, and flight. But though the discovery of Leonardo's manuscripts has proved that several of their results were anticipated by the Italian I cannot believe that the reputation of our countrymen has been thereby diminished, even if patriotism were a serious consideration in scientific or artistic questions. It is the recognition implied, not only of the bond between various special forms of science, but also of the general interest involved in each department of it, which leads me to welcome so warmly the publication in your columns of Professor Pettigrew's valuable collection of examples of spiral formations, the forerunner, I hope, of many others from the same able pen. I should not be alone, for instance, in welcoming some description of the advance in our knowledge of the conchoid curve since Albrecht Dürer, or of the new conceptions of phyllotaxis introduced by Mr. A. H. Church to supersede the theory of Bonnet and the mathematics of Calandrini. I venture on these suggestions because it seems to me that by such publications as that of Jan. 2nd you advance once more the ideal which has so often animated your pages and which I could wish were more widely appreciated elsewhere—I mean the ideal of bringing the results of modern scientific research before the notice of the public in a form which should prove not only advantageous to the general wellbeing but also conducive to the larger amenities of life.

I am, Sirs, yours faithfully,

Jan. 7th, 1904. THEODORE A. COOK.

THE BORDERLANDS OF INFECTIOUS DISEASES AND THEIR MANAGEMENT.

To the Editors of THE LANCET.

SIRS,—This controversy has tended to bifurcate and there are now two distinct points at issue—the soundness of my original contention and the value of isolation hospitals. As to the former, I find myself engaged with Dr. Clement Dukes and Dr. E. W. Goodall, both of whom I must thank for the help in elucidating what may have been obscure in my former communications. May I reply to Dr. Dukes under the categorical heads that I suggested and that he has kindly followed?

1. Here we have an assertion and a metaphor. I will not do Dr. Dukes the injustice of taking his parable of the wheat and the soil as an argument from analogy; that he surely cannot have intended. But I freely adopt metaphor. An agriculturist goes forth to sow. He wheat (bacteria) and sprinkles it on soil (potential pati The wheat germinates and produces, not wheat after kind (bacteria), but something else (diseases)! Is breeding true? I have accepted the metaphor. I that the wheat shall produce wheat, bacteria bacteria. Where does the disease come in? I follow metaphor. The wheat in its growth produces certain in the soil; the bacteria in their growth produce

changes in the patient. These changes we call disease. Still following the metaphor we can see that the changes produced in the soil by the growth of wheat (scarlet fever) may be remarkably like (very little different from) those produced by barley (diphtheria). In a field in which there are much wheat and a little barley the changes in the soil may be still more puzzling. In a field in which both are growing in about the same proportion it may be difficult to say which is the predominating factor in producing the changes noted. A blast of wind carries some ears of wheat, or barley, or both into the next field (infection). The wheat alone may germinate, or the barley, or both, or neither, or much of one and little of the other, or little of the one and much of the other. Thus many sorts of soil changes may be produced in the next field more or less resembling those in the original field. I need not dwell on the comparative fertility of various soils (patients); the importance of this element as a further complicating factor in the problem is obvious. It seems to me that Dr. Dukes has fallen into the error of confusing phenomena with noumena—the manifestations of disease with the essences underlying those manifestations.

2. These I think are described, inadequately doubtless but at a little length, in my paper. Dr. Goodall has very handsomely given the *cachet* of his authority to the accuracy of my descriptions of them; perhaps in view of what has come to light since he may be inclined to reconsider his previous comment on the sad and remarkable nature of the impulse that moved me to set forth such banalities at such length.

3. Now that Dr. Dukes has intimated that bacteria are "poisons" and that "generate" signifies "are the cause of," I do not hesitate to commit myself to the opinion that in the popular sense of the word "cause" particular bacteria are the cause of cholera, plague, tuberculosis, and diphtheria; that is to say, that the presence of a particular bacterium is a necessary antecedent condition. In the philosophical sense—the sense in which Mill used the word, "the sum total of conditions"—of course bacteria are not the cause.

4. Under this head the second question—the value of isolation (aggregation) hospitals—is raised It is my turn to feel a little resentment here, resentment that Dr. Goodall should stigmatise my statement (quoted by Dr. Dukes) as "somewhat loose." In the Metropolitan Asylums Board's hospitals for the last five years for which figures are available—1898–1902—2552 scarlet fever patients suffered from diphtheria during convalescence. The number of diphtheria patients that suffered from scarlet fever during convalescence is not stated, but speaking from my own experience I should say that the proportional incidence was about the same. One would, therefore, probably be not far from the truth in saying that 4000 scarlet fever and diphtheria patients suffered from diphtheria and scarlet fever respectively during convalescence in the quinquennium under notice. I leave out of account attacks of measles, whooping-cough, chicken-pox, and rubella, and ask Was I not justified in referring to the "constant outbreaks"? I should like it to be noted that far from imputing blame I was merely referring to some of the disabilities under which medical officers laboured. Dr. C. Killick Millard has already pointed out the inconsistency displayed by Dr. Dukes in condemning isolation hospitals and resisting an inquiry into them in the same breath. The purpose of such an inquiry would be to investigate the functions of isolation hospitals; how far they succeed in fulfilling those functions; in what do they fail (if they do fail); how far the causes of failure are capable of removal; and, finally, if the net good done by the system does not justify their existence, how far their resources can be diverted into more useful channels. Surely, a most commendable object.

Now, Sirs, on this question of inquiry may I point out that within the last three months the demand for such an inquiry, or a cognate proposal has received support from the following independent quarters:—The Southern Branch of the Society of Medical Officers of Health, *resolution*, Oct. 23rd, 1903. and (I have just been informed unofficially) the North-Western Branch of the same society; the *Medical Press and Circular*, leading article, Dec. 30th, 1903; public expressions of opinion by Dr. A. Mearns Fraser (medical officer of health of Portsmouth), I
officer of health of Leicester), Dr
officer of health of Stockport), I
of health of Windsor), Mr. E D.

W. Moore (Stourport), and Mr. H. Beale Collins (Kingston-on-Thames). Moreover, besides these definite statements of opinions, dissatisfaction with some features of isolation hospital administration as at present conducted has been exhibited by the *British Medical Journal*, leading article, Oct. 3rd, 1903; the *Sanitary Record*, sub-leader, Jan. 7th, 1904; *Public Health*, leading article, January, 1904; public expressions of opinion by Dr. Dukes (Rugby), Dr. F. Graham Crookshank (medical officer of health, Barnes), and others.

The spirit of unrest that manifests itself in these utterances in the short space of three months must surely spread, not only within the profession but also to the public whom we serve and whom we seek to guard. By an independent critical inquiry within the profession we may forestall and even disarm the indignation that seems certain to follow the carrying of these polemics into the public arena. Shall we have such an inquiry or shall we await the greater damnation? I am, Sirs, yours faithfully,

Eastbourne, Jan. 10th, 1904. HUBERT E. J. BISS.

OTOSCLEROSIS.

To the Editors of THE LANCET.

SIRS,—Dr. D. Chalmers Watson's paper in THE LANCET of Jan. 9th, p. 84, proves that aurists have some difficulty in accounting for some of the diseases of the middle ear. He concludes with these words: "While I have just stated that in my opinion we have to deal in all cases of non-suppurative middle-ear disease with a local reaction to bacterial invasion *viâ* the Eustachian tube *we must remember the possibility of the coexistence of an infection by the blood stream. This is probably a factor in many cases, more particularly in those in which there are clinical manifestations of disease usually designated as rheumatism or gout.*" The words which I have put in italics are most suggestive and it is highly probable that the state of the blood has more to do with ear diseases than aurists have yet recognised or are inclined to admit. Even Ménière's disease, which is supposed to depend upon disease of the internal ear, may be found to depend upon rheumatism or gout. Dr. W. Russell contends that arteriosclerosis and the protean troubles that follow in its train depend upon auto-intoxication, which is now receiving much attention at the hands of physiologists. I met with a case of Ménière's disease which in this connexion is worthy of notice. The patient was a man 45 years of age, whose case had been diagnosed by one of the leading aurists in London as Ménière's disease. He was advised by the aurist to cycle to reduce his weight. He continued, however, to have an attack of vertigo and sickness, &c., every week until he gave up eating butcher's meat, when he went eight weeks without an attack and was from home at the time it occurred. The next attack did not occur for eight months, was comparatively mild, and the last he had until he began to eat butcher's meat again. Taught by such experience he determined to avoid butcher's meat entirely and now he has no such attacks, but the noise in the ear remains as before. It is worthy of note that his mother had periodic attacks of vertigo and sickness (which she called "delirium tremens") without any ear symptom whatever.

If then, the worst symptoms of Ménière's disease can be relieved or banished by simply omitting butcher's meat from one's dietary, are we not entitled to conclude that diet must have to do with the causation of the disease, that it, in fact, may be a manifestation of auto-intoxication and be one of "the clinical manifestations of disease usually designated as rheumatism or gout" I commend the study of the question to physiologists and aurists as well as to the general practitioner. I am, Sirs, yours faithfully,

JOHN HADDON, M.D. Edin.

Denholm, Hawick, Jan. 12th, 1904.

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS—You have been so liberal in affording me space in your columns lately that I feel I ought to make the present letter as short as possible I am glad to find Dr. Auld acknowledging that the inspiratory muscles are the chief
taining pulmonary suction and also that their
into account, in addition to passive
and diaphragm, in explaining reflex
Dr. Auld opposes my "oft-repeated

and novel plea that the inspiratory muscles are 'ever busy' and 'moment by moment' keeping up pulmonary tension," on the ground that they do not act during expiration. Surely this is a mere word quibbling. Should I be wrong in saying that the heart is "ever busy" and "moment by moment" keeping up the circulation because each contraction of that doughty organ is followed by a period of relaxation? But as a matter of fact I much doubt the correctness of Dr. Auld's assumption that the inspiratory muscles do not contract during expiration. So far as I can judge from my own organism inspiration is followed not by a sudden but by a gradual relaxation of the inspiratory muscles; during inspiration there appears to be a *crescendo* contraction of these muscles and during expiration a *diminuendo* contraction of them. But whether this is the case or not does not affect the general truth of my contention, for even granting (which I do not) that the inspiratory muscles are relaxed during the whole expiratory phase, their effect in augmenting pulmonary tension above its level at the end of expiration is practically continuous, the mean inspiratory increase in tension being practically equalled by the mean expiratory decrease.

Dr. Auld is of opinion that my "comments on the reflex of contraction are peculiarly unfortunate" but the evidence he adduces in support of this opinion is quite valueless. My contention is that in lungs inclosed within the thorax a momentary contraction of the bronchioles, even to the extent of their entire obliteration, will tend not in the direction of collapse but rather of distension of the vesicles belonging to them. Dr. Auld thinks this view is "peculiarly unfortunate" because it can be shown in the physiological laboratory that lungs whose tubes are made to contract by vagal stimulation diminish in volume. Of course they do when their surfaces are subjected to a positive pressure and not, as when inclosed in the thorax, to a negative one; but even so this diminution in volume does not imply a diminution in the volume of the vesicles: a diminution in the capacity of the tubes would alone suffice to produce it. As Dr. Auld appeals to physiological experiment I would ask him if he has ever seen sufficient pulmonary condensation produced by vagal stimulation to cause a darkening in the fluoroscopic field or a recognisable dulling of the percussion note? Dr. Auld has produced no experimental evidence, nor advanced any sort of *a priori* argument, against the contention he denounces in such *ex cathedrâ* terms. I maintain that a momentary contraction of a bronchiole cannot possibly lead to a diminution in the amount of air contained in the vesicles pertaining to it (by *momentary* I mean lasting a few seconds); and, further, that inasmuch as in the closed thorax the lungs cannot break away from the parietal pleura the vesicles belonging to a momentarily contracting bronchiole will tend to increase in volume by the extent to which that bronchiole diminishes.

I am, Sirs, yours faithfully,

Wimpole-street, W., Jan. 10th, 1904. HARRY CAMPBELL.

A CASE OF ASCITES RAPIDLY CURED ON THE ADMINISTRATION OF IODIDE OF POTASSIUM.

To the Editors of THE LANCET.

SIRS,—A case under the above title which is reported in THE LANCET of Jan. 2nd, p. 24, by Dr. J. A. W. Pereira reminds me of an interesting paper read by the late Dr. J. S. Bristowe before the Medical Society of London on Feb. 15th, 1892,[1] entitled "Observations on the Cure or Subsidence of Ascites due to Hepatic Disease." One of the cases on which his paper was based was that of a woman, aged 24 years, belonging to a respectable and wealthy family. The patient had a profuse attack of hæmatemesis followed by ascites and she was tapped no less than 27 times. At one time the edge of the liver was detected below the ribs and in it a small nodule. This led to the diagnosis of malignant disease of the liver. It was, however, ascertained accidentally that a brother of this patient had been under treatment for some congenital syphilitic affection of the eyes. This discovery led to the suspicion that the lump in the liver might be a gumma. Iodide of potassium and solution of the perchloride of mercury were ordered with the result that the patient attained to better health than she had had for years. This case, together with that reported by Dr. Pereira, certainly emphasises the necessity of carefully considering the possibility of a gumma in obscure cases of ascites and giving the patient full doses of iodide of potassium in suspicious cases.

I am, Sirs, yours faithfully,

Jan. 5th, 1904. F. DE HAVILLAND HALL.

THE POINT OF PRIMARY GONORRHŒAL INFECTION IN THE FEMALE.

To the Editors of THE LANCET.

SIRS,—On previous occasions you have courteously permitted me to encroach on your valuable space and I now ask again the same privilege in order to make a few observations on a subject which has interested me very much during the 25 years I have had the honour of belonging to the profession. I write in the interest of the general practitioner who, like myself, may be beyond the pale of laboratories, &c., and not in any sense pretentiously. I say this not to disarm criticism but rather to court it from those who are in a position to teach us.

There is a great number of women, especially primiparæ, who suffer from fever after childbirth and in whose cases it is simply impossible to lay the blame on the accoucheur or any other person who has participated in the event. These cases in the past oftentimes were recorded as "idiopathic," or the physician, after going over every step in the conduct of the labour and finding nothing wrong so far as he could judge, decided that there must have been a leak somewhere and mutely blamed himself for some act of omission or commission which he could not recall. Nowadays the word "idiopathic" has almost, if not quite, disappeared from our vocabulary, but the cases still remain to puzzle the unfortunate medical attendant and they are those to which I desire, with your permission, to draw attention.

For a number of years I have been in charge of the venereal hospital of this city where all the licensed prostitutes are examined twice a week and where the "free lances" captured by the police are taken, often in squads every day, for examination. Thus several thousand examinations are made annually. When any one of these prostitutes, licensed or clandestine, is found suffering from any form of venereal disease she is detained for treatment until recovery. The first thing to be noted in such a service was the fact that almost every prostitute who had been such for any time suffered from cervical endometritis. This was no new discovery, but as time went on I noticed that women with urethritis or vaginitis almost invariably had endometritis (cervical) also. The combination might not even then have aroused any particular line of thought, but have been accepted as quite *en règle*, had I not observed on several occasions a woman "slated" for cervical endometritis a few days later developing a urethritis without in the interval having had any opportunity for sexual contact. On making a microscopic examination of the cervical discharge in a few of these cases of endometritis only I was able not infrequently to recognise the diplococcus of Neisser and even to make cultures. Many times the microbe could not be demonstrated but abler men than I have been baffled, especially if the case be chronic. After eliminating all doubtful cases of former infection there have remained 154 complete observations on indubitable first "doses." As a natural consequence I was led to conclude that the teaching of both the English and French schools in which the vagina or the urethra is said to be the starting point of infection was *erroneous* and that the primary *point of attack* is the cervix, the other parts being contaminated secondarily.[1] In other words the contagion descends and does not ascend. This is the rule and the exceptions are rare and accidental. Has it been demonstrated that the gonococcus has the power to climb or of innate locomotion? I herewith emphatically express a doubt of the direct surface extension of gonorrhœa from the vulva upwards to the womb, and my object is not to raise a quibble but has a very serious bearing on the possibility of preventing the terrible after-results in those women who have unfortunately contracted the disease. At present I believe our energies are all misdirected We direct our efforts to the treatment of the urethra or vagina hoping to avert the infection of the uterus when in reality the evil has already been consummated.

---

[1] THE LANCET, Feb. 20th, 1892, p. 422

[1] In the German Congress of Gynæcology held in Vienna in 19 Wertheim had the audacity to give it as his opinion as against al comers that "next to the urethra the most frequent site of gonorrh infection is the uterus. The infection of the uterus frequently place directly and in many cases it alone is infected." Since then I not know that he has advanced. I go a long step forward, putti womb in the forerank and the other organs well behind. I across the record of this special congress after having completed above communication. Had I known in time that anyone had so near my own opinion (so near and yet so far) I should not written this letter.

There is no need for me to speak of the teachings of Schroeder, Pozzi, Doléris, Bumm, Steinschneider, Goenner, Döderlein, Strauss, Kaltenbach, Fehling, and a host of others who recognise the gonococcus as one of the causes of puerperal septicæmia, in contradiction to the opinion of Czernewiski[2] that the streptococcus pyogenes causes all the septic lesions of parturition. Many of these have been hovering over the idea above indicated but have never asserted it as a fact Perhaps they have had some reason for not interpreting the observations they made as I have done, and I may justly be censured as an incompetent observer. I am cognisant, too, of the work of recent years on the gonorrhœal infection of certain organs through continuity of mucous membranes but at least these membranes are differently "shod" than the vagina, their secretions are not inimical to the life and propagation of the gonococcus as is that of the vagina, nor are they inhabited continually by a horde of other germs which are ready to prey on a succulent animalcule. The vagina, in its upper fourth especially, and more so in pregnant women, is a perfect nest for pathogenic microbes, for the most part attenuated (Winter) and deprived of their virulence, except when aroused by some special cause such as the invasion of the gonococcus Then they arise in their might to expel the invader. In the male urethra, for example, things are very different. It is lined throughout with columnar epithelium except at the meatus where it is laminated (Gray). Its mucous membrane is full of all kinds of crypts and ducts lined with the same kind of epithelium, forming underground railways, so to speak, which can serve for the conveyance of the microbe to the posterior urethra, prostate, &c., and which serve, too, as shelters from its enemies, chemical and otherwise[3] Cases have likewise been reported of the direct passage of the germ up [illegible] ucing uretero-pyelonephritis. [illegible] this requires first a gonorrh[illegible] nsider that the microbe simply crosses the gap by means of the urine, thence into the ureters, the mucous membrane of which is exactly like that of the urethra, and so up into the kidneys. This mode of infection I do not accept as proven, not even by Arpad Gerster's celebrated case[4] On the other hand, the ascent through the lymphatics in such cases is easily understood owing to the peculiar course of the ureteral lymphatics, their mode of penetrating the renal cortex, and their distribution in the spaces between the uriniferous tubules.[5] Albarran[6] shows that this lymphatic communication could not be interrupted even by ligating the ureter. The other mode of transmission is the circulatory or metastatic, as we have it in almost every organ in the body—in the heart, the brain, the spinal cord, the joints, the muscles, and the *tendons*; even in the blood stream itself and in the milk of nursing women have living gonococci been demonstrated.[7] By these two paths it is an established fact that an *intercurrent gonorrhœal nephritis* may be produced, but it appears still more than doubtful that the gonococcus can reach the kidney by simple locomotion. Much less then ought we to expect to see the uterus infected from the vagina (*for reasons above stated*) by [illegible] nor by the [illegible] e lymphatics, belong to s[illegible] blood-vessels [illegible] mb.[8] In the virgin bride it is true that the infection may enter the system through the breach of continuity made in rupturing the hymen, but as the hymen is a part of the vagina, and as a true, special, and independent membrane does not exist (Budin) what is said of the vagina is applicable to the hymen.

In the act of coition the uterus does not remain passive. It has its orgasm, too, being at the physiological moment violently contracted—that is, when in its normal position. An anteverted uterus, for example, is too degenerated in its musculature to be able to get up a respectable contraction, and hence such uteri are as a rule sterile. When this physiological contraction passes off and there supervenes the condition of relaxation a strong suction is made which draws the semen just deposited in the cul-de-sac of Douglas into the cervix, where the columnar ciliated epithelium wafts the zoosperm onwards and inwards. Suppose now that the woman's companion has gonorrhœa, the pus of which must naturally be ejaculated from his penis together with the semen, what is lacking for the development of a cervical clap? Both are sucked in together and the alkaline mucus of the cervical canal favours the gonococcus while destructive to all other microbes introduced from without save the bacillus of tuberculosis. Once introduced into the sacred precincts only time is necessary for the production of those conditions first made known by Noeggerath who by his work made us revise the pathology of the female pelvis.

Not the prostitute alone is victimised in this manner. The bridal bed is in many cases as true an altar of sacrifice as is any funeral pyre provided by the Hindoo. How often has it been necessary for men to postpone their wedding day on one pretext or another in order to get rid of an inconvenient recent clap? How often have the said claps been "cured" by some lazy or ignorant member of our profession (for there are such), or by some druggist, or by a prescription loaned for the occasion by some tried friend. The "running" has stopped apparently and no one has given the prospective groom the two glass test or the beer test and so, guiltily innocent, he gets married. We all know of such cases, but how many are there that we do not know of. The profession is not entirely blameless in this matter. Our teaching should be as clear on the d[illegible] to an innocent woman as it is [illegible] medical men, if any, fail to w[illegible] the dangers that are ahead ar[illegible] cure, but we fear that many d[illegible] clients, when in truth the danger is possibly more serious in these than in those. As far as the wife is concerned, perhaps, a syphilis were a kinder fate and as for the offspring pathology has not yet said nearly its last word. In the case of such a pair it follows, as the night the day, that the poor woman contracts the disease. Her mucous membranes are still soft and tender and the disease has a splendid field for cultivation. If she had had several children she might, perhaps, have escaped paying the full penalty, but being a nullipara she is a sure subject for the hideous catastrophes which follow fast, that is, if she should conceive in the early days of her marriage On the other hand, if she does not become pregnant very soon she is likely to be sterile, for she is then in a similar case to the prostitute whose chances of conception are relatively very slim. The Spaniards have an adage to explain this: "El camino bien pisado no da grama" ("The well-trodden road does not produce grass"), but I believe the sterility in such cases to be more often due to the cervical inflammation which prevents the impregnation

It is not the object of this letter, however, already too [illegible] in women generally but only [illegible] children. Suffice it to say that [illegible] allest of the woes which befall the infected barren wife The diseased pregnant woman may have little to indicate her proximate peril until it is upon her. Any troubles she may have during her pregnancy are set down in good faith to her condition by herself, by

[6] Annales des Maladies des Organes Génito-urinaires, p. 503, 1899.

[7] I am indebted to a paper by Dr. Le[illegible] ology of [illegible] subject, [illegible] "direct [illegible] to ap-

[illegible] mphatics of the Kidneys (Gray). The lymher wise good neighbours, and even by her medical adviser. And so she goes patiently on, like the doomed ox, to her fate. In the 24 hours more or less of labour, while finally expelling the child, the uterus in its upheavals has had all its sinuses opened to receive the poison which may have lain dormant during the foregoing months.[9] And now the woman has an attack of "idiopathic puerperal fever." That is all. It may not be the gonococcus itself which produces all the turmoil, indeed, very likely it is not, but the toxins, which are quite capable of finding their way either by the tubes or preferably by the uterine lymphatics to the peritoneum, where they have things all their own way. I have notes of 30 cases of primiparæ, with history of infection, who suffered from this form of puerperal fever. These were all personal cases and the writer can vouch for the aseptic management of the labours. In the after light thrown by more recent studies I can recollect many others not noted as such who undoubtedly belonged to the same category. The patients in these cases often do not die, they only become lifelong invalids. In their after-life these martyrs generally suffer at each menstrual period. There is always some trouble; even a fresh urethritis has been seen to occur month after month at that epoch. These patients rarely become pregnant a second time, but if they do they are liable to abort[10] and a hard time they have, running the same gamut as in their confinement at full time.

In my notes in prostitute cases there are several of *puellæ* with chronic endometritis who followed their vocation without giving disease to their "friends" during the most part of the month, but who invariably infected those men who had the fortune to enjoy their embraces on the nights immediately succeeding menstruation. These are the cases, too, where men are infected by women while menstruating. It is not the menstrual fluid (I am not forgetful of M. Gautier's researches on that liquid) which gives the urethritis, but the stored-up gonorrhœal pus or its equivalent which at that time comes down into the vagina together with the blood. Cases of urethritis contracted from women with leucorrhœa will likewise stand investigation many times. That such cases are of a benign type as a rule simply indicates that the virus has been attenuated *more homœopatico*. It is taught that when an organism has lived a saprophytic existence for some time its virulence is greatly diminished. Still, some of the most virulent cases I have ever had in my practice were said to have been derived from "whites." I am, Sirs, yours faithfully,

Guatemala City, Central America. J. H. ARTON, M.D.

THE ADMINISTRATION OF CHLOROFORM TO MAN AND TO THE HIGHER ANIMALS.

To the Editors of THE LANCET.

SIRS,—Will you permit me to reply briefly to Dr. J. Blumfeld's criticisms, in THE LANCET of Jan. 9th, p. 122, of some remarks of mine in your issue of Dec. 19th, 1903, p. 1757? I must have very imperfectly expressed my meaning since Dr. Blumfeld attributes to me the view that the patient's safety does not depend on the care and skill of the anæsthetist but upon the particular instrument he uses. This amounts to an almost Gilbertian suggestion that the anæsthetist's responsibility would be limited to turning on the supply tap of his apparatus at the commencement of the operation and turning off the tap at its conclusion, while in the interval he allows his attention to wander. Dr. Blumfeld very rightly, as I venture to think, controverts this view with an admirably reasoned argument in which the suggestion is carried to its logical conclusion—absurdity. Unfortunately, however, I do not hold such a view and did not, as I think, advance it. The middle paragraph of my letter contained evidence of my recognition of the existence and importance of "that uncontrollable factor—the character of the respiration."

My contention was, and is, that the anæsthetist is in a much more scientific position when he supplies to the patient a vaporous mixture the exact quantitative composition of which he not only knows but can vary with precision as the necessity of the case requires and when he can completely control the quantity of such mixture supplied than when he is administering a mixture the quantitative composition of which he can only guess at and can only vary its composition by the same inaccurate means. It seems to me that in either case every whit as much care and skill is required during administration. Since of those two elements of danger in the production of anæsthesia, the character of the respiration and the strength of the vaporous mixture, the former cannot be controlled, while the latter apparently can, then the extent to which this control can be exerted is a measure of the extent to which the danger from this element can be minimised. Such a view does not imply that all danger can be removed from the operation of administering an anæsthetic.

Dr. Blumfeld's remarks on the limitations of the various forms of apparatus mentioned are valuable, particularly so as they are probably the result of his experience. An apparatus which does not allow sufficient variation of dosage would indeed be inefficient. With his concluding remarks on the necessity of experience and teaching in the use of anæsthetics for all who may have to administer them I am in entire agreement. I am, Sirs, yours faithfully,

Bromley, Kent, Jan. 9th, 1904. W. J. LINDSAY.

GLANDULAR FEVER.

o *the Editors of* THE LANCET.

SIRS,—In connexion with Professor J. W. Byers's article on Glandular Fever in THE LANCET of Jan. 9th, p. 84, it may be of interest to give a short note on a somewhat similar epidemic which occurred here in September last. Seven cases came under my notice and common symptoms in all were as follows: (1) rise of temperature; (2) slight sore-throat; (3) a unilateral swelling of the glands in the neck situated in front of the sterno-mastoid muscle and just below the angle of the jaw; and (4) a discharge of pus and mucus from the nose. Five of the cases had a purulent discharge from the ear on the same side which commenced at the same time as the swelling of the glands; these were the first five cases that occurred, the last two not having any discharge from the ear. The first two cases were the most severe, an intense cellulitis forming round the swollen glands. This was incised but practically no pus escaped. A swab was taken from the throat of the first case and sent to be examined for diphtheria but proved negative. Films were made of the pus from the ears and wounds and on being examined microscopically I found that the only bacterium present was the pneumococcus. I got Dr. F. W. Eurich, the city bacteriologist, to grow cultures from the pus and he confirmed my result as to the condition being a pure pneumococcal infection and remarked that he was struck with the fact that the swab previously sent to him had also given an almost pure culture of the pneumococcus. As several other cases of pneumococcal infection, such as abscesses in the vicinity of the knee-joint, a case of mastoiditis, &c., have since come under my notice here, it would be of interest to know if the abnormal atmospheric conditions of the last few months have had any effect in causing this coccus to take a special action like the above.

I am, Sirs, yours faithfully,

J. KENNEDY MATHESON,
House Surgeon, Children's Hospital, Bradford.

Bradford, Jan. 11th, 1904.

RADIUM IN THE BATH WATERS.

To the Editors of THE LANCET.

SIRS,—So much public attention has lately been drawn the presence of radium in our thermal waters that I sl like with your kind permission to say a few words as to bearing that this substance may have upon the h, therapeutics of Bath. Into the general facts as to the in which the discovery came about it is not necessary to enter, they have been sufficiently described in the lay press. There is one point, however, which calls for attention. The presence of radium was demonstrated in the sediment which deposits in the tanks and baths, and not as is imagined by some in the sands which are washed up with the water as it rises to the surface. Whether it is in these as well is not yet known, the interesting fact remains that radium is in the waters themselves. The sediment which was examined is the same that may be seen collecting in the corners of an empty bath, especially at the Mineral Water Hospital, and it also gives the drinking glasses their characteristic rusty stain. It follows then that radium in homœopathic doses is taken into the system when the water, which is pumped straight from the spring to the glass, is drunk. It is hardly necessary to point out that the presence of radium in the water does not alter and does not extend the list of those forms of illness which are benefited here. The medical profession will fully recognise this fact and it is to be trusted that the laity will not be encouraged to entertain hopes on this subject which are doomed to disappointment.

---

[9] Menge and Kronig say: "Gonorrhœal puerperal fever is to be regarded as due to an infectious process, already existing in the body, not as an example of autogenesis."

[10] The tendency to abort observed in the gonorrhœal woman comes from a "placentitis decidualis" (Vial). It is worthy of note that it is suspected, if not quite puerperal convulsions are the result of a nepl ine gonorrhœal infection, conveyed probably l be remembered that the terminal branches vein empty into the left renal vein. To connect our former empirical ideas of the pathological condition underlying these cases (pressure on the renal veins) we have only to go a step further and, given a stasis from pressure, it is easy to understand how the gonococci from the womb reaching this point and being detained and finding a suitable culture medium (human blood being the best) should spread and in colonies invade the kidneys. This may be considered fanciful but I leave it so.

The question is, however, of interest as to whether or not in radium we have solved the hitherto unknown quantity which determines the therapeutic action of our waters. There are some members of the medical profession who do not believe that there is any special therapeutic action in waters which, like those of Bath, contain very little mineral matter and who think that, except perhaps for the influence on the mind, any water would do as well. Such, indeed, was my own opinion when I first went to the Mineral Water Hospital. In the past 14 years, however, I have seen many cases in which after fair trial elsewhere benefit has at last resulted here. If we have not known, and do not know, to what the benefit is due, still using the waters empirically, we have only been doing with them as we do with nearly all the medicines we prescribe, and experience has justified our action. So little is known of radium, and nothing of its action when taken internally, that we are at least justified in thinking that its presence may explain what we have so far been unable to understand.

In the current number of THE LANCET the question is asked as to whether radium is the cause of the heat in our thermal waters. I think with the direct evidence of volcanic action before us as supplied by the presence of lava in the sands it is not necessary to seek further for an explanation of the heat. I am, Sirs, yours faithfully,

Jan. 11th, 1904. PRESTON KING.

*** Dr. Preston King must have misread the annotation in our issue last week on this subject. The question there asked was "Can the healing properties of the waters have anything to do with radio-activity?" There was no suggestion made of radium offering an explanation of the *heat* of the waters.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Pasteur Institute at Kasauli.—The Bombay Government on Hospital Fees.—The Plague Epidemic.—The French Government and the Destruction of Rats.

AN excellent record is presented of the third year's work of the Pasteur Institute at Kasauli. Inoculation for rabies s becoming better recognised by the natives of India and although the great distance of some parts from Kasauli acts as a deterrent to many the facilities for remaining under reatment have been well arranged for and are highly appreciated. Out of 584 patients treated there were only ix failures and these occurred entirely in the case of persons bitten by animals suspected of rabies but not proved to have had the disease. Among 104 patients bitten by animals proved to be rabid and among 70 patients bitten by animals certified as rabid there was not a single case of failure. The animals by which the bites were inflicted were 500 dogs, 59 jackals, three cats, one mule, and ne fox. Antirabic serum has been prepared with a view to improve the treatment in badly bitten and late cases by diminishing the time required to produce immunity. The animals used for this preparation are young healthy ponies which have been prepared with large doses of "fixed virus." Another stroke of good work has consisted in the preparation of antivenene on a large scale. Over 1000 bottles have already been distributed and Lieutenant-Colonel D. Semple, R.A.M.C., expects to be able to supply the demands from the whole of India. Typhoid fever "vaccine" and anthrax "vaccine" were also produced and diphtheria and tetanus antitoxins are in course of preparation. I am very pleased to hear that the financial position of the institute is sound and that it is becoming an establishment for the advancement of bacteriological science as well as a teaching centre.

A recent resolution of the Bombay Government upon the question of fees at hospitals supported by the State from persons who are not to be classed as poor determines that no change shall be made at present. It is considered that if the people were deprived of European medical advice by charging more than nominal fees they would resort to ignorant quacks and native botanists. Persons are considered as poor who are in receipt of less than 20 rupees (£1 6*s.* 8*d.*) per mensem. Others slightly better off have to pay small sums for food or for special accommodation or attention. A further class of persons is made to include those who have to pay for advice and treatment at the dispensaries. The Government is considerate to practitioners and lays it down that where there is a qualified private practitioner the collector of the district may fix such rates as shall encourage private practice and discourage the use of State-aided dispensaries by persons able to pay.

The plague mortality throughout India fluctuates between 16,000 and 18,000 but for this week 17,295 deaths are recorded. For the corresponding week last year 14,200 died from plague. There is a slight increase in the Bombay Presidency and in the United Provinces. The prospects are very disheartening because the returns show how widely the disease has spread and how severe it is in places. In the Bombay districts the number of deaths as compared with the seizures is appallingly high but this may be because the deaths only are recorded and very few living cases come to notice. In the crowded populations of the Central Provinces and Berar the deaths are about ten times as numerous as in the corresponding period last year. Central India has come on the register this year and reports about 1000 deaths weekly. Bengal is once more showing a recrudescence—the Patna district especially suffering. The seaports of Bombay, Calcutta, Karachi, and Rangoon return but few cases. In Kashmir (Srinagar) the plague is developing very rapidly and severely, the type being pneumonic. All the cases are fatal. The outbreak is said to have spread from a common origin. Out of the 30 medical officers engaged two years ago for inoculation work in the Punjab for an impossible scheme only about five remain. In one or two districts last year some thousands of people were inoculated but in all the others practically nothing was done. At present there is nothing doing but the recrudescence has not yet started in the Punjab.

By a decree of the French Government recently circulated in India the destruction of rats on all vessels arriving from an infected port is compulsory. If done in port some recognised method must be adopted or it will be done by the port authorities if desired. Considering how infested with rats nearly every vessel is and the farcical regulation of some companies for keeping a few cats on board to absolve them from liability against action for the destruction of cargo this decree promises to accomplish benefits other than against plague.

Dec 25th, 1903.

METROPOLITAN HOSPITAL SUNDAY FUND.—At a meeting of the Council of the Metropolitan Hospital Sunday Fund, held at the Mansion House on Jan. 7th under the presidency of the Lord Mayor, the Rev. Prebendary Ridgeway, Mr. R. de Q. Quincey, and the Rev. A. Fleming were appointed members of the general purposes committee to fill vacancies. The committee of distribution is now constituted as follows: the Lord Mayor, Sir Sydney Waterlow, Lord Stamford, Sir Savile Crossley, M.P., Sir William Church, K.C.B., P.R.C.P. Lond., Captain J. Cundy, Mr. Robert Grey, Mr. Herman Hoskier, Mr. F. H. Norman, and Mr. Alfred Willett.

TRIPLE COMPULSORY VACCINATION IN FRANCE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

No. I.—EFFECT OF THE NEW LAW ON FOREIGNERS.

A GREAT change is being gradually wrought in French institutions. The need of practical legislation in matters of public hygiene has long been keenly felt. The existing laws were of a vague character and left matters too much to the discretion of elected bodies. The latter, on their side, while often recognising the necessity of action, were too much at the mercy of their electors to venture on any drastic measures. But now at last a law has been enacted which constitutes a Public Health Act and this orders and compels the local authorities to put into practice measures which for the most part were but subjects of discussion. As often happens when a legislature is behind the age it is not content with a gradual advance but takes a sudden leap and finds itself first where it used to be among the last. This is the case in that portion of the new French Public Health Act which deals with vaccination. At the International Congresses of Hygiene the French representatives used to speak enviously of Great Britain, Germany, and other countries where vaccination is compulsory. Then they apologetically explained that though vaccination was not *de facto* obligatory every effort was made to render it indispensable in practice. Thus education was obligatory but no child was admitted into a school who had not been vaccinated. Military service was obligatory but no soldier was allowed to join his regiment who had not been vaccinated. In all State employments and in the employment of railway companies, &c., no one was accepted who had not been vaccinated. Nevertheless, the French delegates at the Congress felt sorely the inferiority of the position. All this was mere manœuvring, not to circumvent the law, but to make it appear as if a law existed when in reality there was no law. All this is changed now. Not only is there a law but it is a triple-barrelled law, for it compels every French subject and every foreigner living in France to be vaccinated not merely once but three times. Here is the actual text of the law of Feb. 15th, 1902, on the protection of public health as modified by the law of April 7th, 1903, which is to come into force one year after its promulgation:—

> Article 6.—Anti-small-pox vaccination is obligatory during the first year of life, as also revaccination during the course of the eleventh and the twenty-first year.
>
> The parents and tutors are personally held responsible for the execution of this measure.
>
> Regulations will be issued by the public authorities in keeping with the advice given by the Academy of Medicine and the Consultative Committee of Public Hygiene of France fixing the measures necessary for the application of the present article.

Thus it is now no longer permissible or legal for a person residing in France to endanger the health of his neighbours by refusing to take the precautions that will most probably prevent his becoming a centre whence small-pox may be spread to others. At Nice, some two years ago, I remember describing the perplexities of the authorities in regard to an English antivaccinationist. When the epidemic of small pox broke out in this town during the season of 1901 and 1902 the victims were principally unvaccinated Italian labourers. The garrison, consisting of 3800 soldiers, was at once revaccinated, and though the soldiers when on leave generally frequented the part of the town where small-pox was most prevalent not a single case occurred among these troops. But adding to the soldiers the men and women employed at the State tobacco factory and the railway and tramway lines there were altogether some 10,000 persons who could be compelled to be, and consequently were, revaccinated. Out of these 10,000 persons 14 contracted small pox before they were revaccinated and two others managed to avoid being revaccinated and they also had small-pox None of the others suffered from the disease and thus 10,000 persons lived in the midst of a small-pox epidemic and after revaccination there was not a single case of small-pox among them. It was in the face of these facts that an English lady, calling herself a Christian Scientist, went about among the American and British residents at Nice persuading them not to be revaccinated. The authorities were perplexed. On the one hand they were anxious to show the greatest courtesy and consideration to all foreigners who went to winter at Nice, but the epidemic was frightening their winter guests away and here was a lady doing her best to increase the prevalence of the disease. Suggestions were made to expel her from the territory, at least of Nice, if not of France. But then no law had been broken or defied since vaccination was not obligatory; it would therefore seem a very arbitrary act to compel the Christian Scientist to leave the town. However, the difficulty was solved in a very effective though untoward manner. This lady had, in any case, the merit of consistency, for she would not allow herself to be revaccinated. Thus unprotected she contracted small-pox and died in a few days and the authorities were relieved in this suggestively dramatic manner of the embarrassment that her presence and action had created.

Now, with the new law no such difficulty would be possible. To persuade a person not to be vaccinated is to persuade him to break the law and therefore action can be taken. But apart from this general principle the regulations to which allusion is made in the third clause of Article 6 quoted above have now been issued and they contain a special article relating to foreigners. Not only do the regulations apply to all persons without any distinction being made with regard to the nationality of such persons but Article 10 expressly states:—

> The foreigner who shall have established his residence in France is subjected, for himself and for his children, to the prescriptions of the present regulations in the place where he resides.

This enactment will be found in the decree of July 27th, 1903—published in the *Journal Officiel* of July 31st, 1903—"dealing with the public administrative regulation of vaccination and revaccination in virtue of Article 6 of the law of Feb. 15th, 1902." This decree is signed by the President of the Republic, M. Emile Loubet; by the President of the Council and the Minister of the Interior and of Public Worship, M. E. Combes; and by the Minister of Justice, M. Vallé Then there is also a ministerial circular to the prefects, dated August 7th, 1903, dealing with compulsory vaccination and revaccination according to Article 6 of the law of Feb. 15th, 1902 This circular has for its object to explain the various articles of the regulations and under the heading "Application to Foreigners, Article 10," there occurs the following passage:—

> All the prescriptions which precede are applicable, in virtue of Article 10, to foreigners, for themselves and for their children The importance of this assimilation from the prophylactic point of view could not, Monsieur le Préfet, escape your notice. If the foreigners who come and install themselves on our territory are [illegible] benefit by the guarantees which the application of the new law will give to the French populations it is just that they should not be able to escape from the obligations which the law imposes so as to [illegible] [illegible] id this, too, in such a manner as would [illegible] whom these foreigners propose to live [illegible] . . . are henceforth inexcusable.

In other words, foreigners will not in future be allowed to endanger the French people by living in their midst if they have not been properly vaccinated. Doubtless it will be somewhat difficult to apply such a regulation to mere tourists but the law will be enforced in exactly the same manner on the foreigner residing in France as on French subjects themselves. All this will take time to organise and to carry out but now the necessary regulations and instructions have been issued and the first steps in this direction have been taken.

University Lectures.

ON Jan. 5th Sir Oliver Lodge, D.Sc., LL.D, F.R.S., Principal of the University, delivered two lectures in the town hall on the subject of radium. At the first of these lectures, which was delivered in the afternoon, the Chancellor, the Right Hon. Joseph Chamberlain, presided and most of the members of the staff were present in academicals. The hall was crowded with an audience consisting of governors, donors, and other citizens. Admission was by tickets which were, for the most part, distributed gratuitously, but a certain number for reserved seats were sold in order to defray the necessary expenses of the occasion. There was a great demand for these tickets and it is rumoured that much higher prices than those charged by the University were offered to those who, by early application, had come into possession of them. The lecture was illustrated by experiments and by lantern slides. In the evening Sir Oliver Lodge repeated the lecture for the benefit of working men who were admitted free. On this occasion the chair was taken by the Lord Mayor who at the conclusion of the lecture very heartily thanked Sir Oliver Lodge for his address. A circular has been sent out to members of the medical profession in the district stating that at the request of the Dean of the Faculty of Medicine Sir Oliver Lodge has consented to deliver a course of four lectures on those parts of physics which are of especial interest at present in connexion with medicine. The lectures will be delivered on the four successive Thursdays in February in the medical theatre of the University and will deal with the following subjects:—(1) Production and Properties of Cathode Rays; (2) Production and Properties of Roentgen Rays; (3) Production and Properties of Ultra-violet Light; and (4) Production and Properties of High-frequency Alternating Currents. Admission will be by tickets which are obtainable gratis on application to the ean of the Medical Faculty.

Notification of Small pox: a Curious Case.

The following correspondence opens up a matter of con-derable importance in connexion with the question as to bether the health officials, when aware that a domestic rvant has been in contact with a case of small-pox, are ound to inform the employers of the servant or should, s they did on this occasion, allow them to remain in norance. The gentleman in question in this case would ertainly seem to have had just grounds for complaint in at he was not apprised of the state of affairs, that his aid was not obliged to submit herself to vaccination, and hat he has been subjected to great anxiety, annoyance, and xpense on account of the failure of the health officials to ive him that information which it certainly seems that it vas their duty to afford him. The case is fully explained in he following letter addressed to the health committee:—

> One of my maids spent the evening of Sunday, Nov. 22nd, at her rother's house. On the Monday or Tuesday following one of the nmates of that house was removed to the small-pox hospital. My naid was traced and noted by your officials as a "contact" and was isited at my house by one of them. She was taken ill on Friday ast (Dec 4th), was seen by my own medical man, who at once called n Dr. McCrindle, and her case was diagnosed as one of small pox nd on the same evening she was removed to the hospital. I know othing of the case nor of what had transpired until I returned ome on Friday evening but, fortunately, my wife was in the ouse and her promptness has, I trust, prevented any serious conse-uences. The fact, however, remains that no communication, official r otherwise was made to me or to my wife of the case, nor were ny steps taken by your people to get the girl vaccinated or to have er clothing disinfected. This omission has unnecessarily involved ive other people in the danger of infection, has made my house uspect, and has thrown upon my wife and myself a burden of anxiety which it is impossible to exaggerate. I am unable to discover any ossible excuse for such treatment and I shall require that the matter e thoroughly investigated.

The following is the reply of the chairman of the health committee and it certainly seems scarcely calculated to give confidence to householders that their interests are being considered by the health committee as they might be considered:—

> The health committee at their meeting yesterday had under consideration your letters of the 7th and 9th inst. They have very carefully inquired into the whole circumstances which have occurred in [illegible] st [illegible] it [illegible] ve [illegible] of your servant's contact with the disease. If she had been sent away from your house at the time that the medical officer of health became aware of her contact and had subsequently developed small pox, it [illegible] ised vaccination and dis- [illegible] at the time the medical [illegible] g —— under observation [illegible] el that it is a matter of [illegible]

It will be observed that the letter makes no attempt to explain why the employers were left uninformed as to the risk which their servant had run, still less does it state why the health officials neglected to insist upon her being at once revaccinated. In the event of their having suggested re-vaccination and having met with a refusal it would have been doubly their duty to inform the employers as to the state of affairs.

Sister Dora Convalescent Home.

The convalescent home founded in memory of the lady best known in Walsall and elsewhere as Sister Dora seems to be in financial difficulties. It is situated at Milford, near Stafford, and a meeting has recently been held there to consider the report of a county committee which was appointed some time ago to consider whether the advantages of the home could not be retained for Staffordshire, a proposal having been made that the services of the institution should be placed at the disposal of patients from Leicestershire and that it should be managed by a committee representing that county. The committee reported that in the past the home had mainly relied for its support on the hospitals of the county but that with two exceptions the response made to recent appeals had been disappointing. Some of the leading hospitals had, however, not been able to give a definite answer on account of the short time which was allowed to them for arriving at a decision. It was thought that some further assistance might be expected from these sources. The Wolverhampton Hospital committee had passed a resolution that in the event of Lord Dartmouth who is Lord Lieutenant of Staffordshire and was chairman of the committee in question, being able to give an assurance of support from the county of Stafford of a subscription list of £250 per annum at least it would be able to take over the home under certain conditions The Staffordshire General Infirmary committee under certain conditions would guarantee £100 a year. In addition the committee had promises of about £150 but some of these were "ear marked" and must not be counted twice over. It had promises of further contributions which would amount to about £50 With these facts before it the county committee passed a resolution that if more time were allowed there would be no difficulty in raising the necessary income as no effort had yet been made to canvass the county systematically. The report having been considered it was proposed that a further period of six weeks should be allowed to the county committee but that if at the expiration of that time it should appear that the amount required by the Wolverhampton Hospital committee was not forthcoming the committee should lease the home to the Leicestershire authorities. The Bishop of Shrewsbury moved an amendment that the condition and affairs of the home should be referred to the Charity Commissioners for their consideration. This was seconded by Sir Thomas Salt but met with no other support and eventually the motion as above was carried by 12 votes to two.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

A Portable Bath Fatality.

ONE can scarcely take up a periodical without seeing advertisements of various portable hot air or vapour baths. Presumably, therefore, the sales must be numerous enough to pay more than the cost of advertising, and yet it is seldom that any accident from their use becomes publicly known. It is, however, clear that they ought to be used carefully and with common sense. This is shown by the evidence given at an inquest held on Jan 6th in Manchester. A young woman 21 years of age went upstairs to have a vapour bath in what the father described as "a folding bath, about three feet square, with a sloping top and a hole for the head." In a few minutes she called out "Oh, mother, I am burning," and rushed out of the bath room. She was terribly burnt, was attended to by a neighbouring medical man, and then taken to the infirmary where she died in a [illegible] that she was [illegible] l as the lamp [illegible] and began to pour in some methylated spirit when it exploded. The father said that the sides of the lamp would be nearly red hot and she did not wait till it had cooled. Nothing remained of the bath but the bare wire framework. The bath room was a "charred mass" and the windows were blown out. The coroner, Mr. E. A. Gibson, made some strong remarks on these baths which, he said, it was "highly reprehensible to put on the market" when it was obvious that they were nothing but death-traps. "He had known in his own experience other cases where people had been burnt under similar circumstances, though not fatally. He could not speak strongly enough against it." These baths are evidently dangerous things and if used at all should be used with great caution.

How We are Undermined.

Reverting to the thoughts suggested by the Hanley tragedy, disused mining shafts are not the only dangers that beset our paths. In Blackburn the other day a girl was almost engulfed but rescued just in time to save her from that fate. She was, however, so seriously scalded that she soon afterwards died. The hole where the ground gave way was soon enlarged considerably by the falling in of the road. It is thought that the occurrence was caused by a leakage from a collapsed brick culvert into which a factory discharges waste hot water. It is not often, perhaps, that education suffers from school-houses sinking, but at Northwich, well known as a centre for subsidences, a school has just been closed from this cause. It may be in the recollection of some that a few years ago at Northwich a man was in a stable attending to a horse when the floor suddenly gave way and though the man was just able to escape the horse was swallowed up and seen no more. Such facts as these should make the authorities more alive to the dangers associated with the underground operations necessary for our comfort and convenience and more careful in seeing that all possible means are used to guard against these dangers which are very likely to become more common as time brings change and decay.

Notification of Pulmonary Tuberculosis.

The Medical Guild of Manchester has protested against the proposal of the city council to seek Parliamentary powers for the compulsory notification of pulmonary tuberculosis. It states that medical men realise that public opinion is not ripe for such a "drastic proceeding" and considers that "the present system of voluntary notification, which gives the medical attendant discretionary powers in his private practice," is sufficient. It suggests that it would be well to await the results of the experiment of compulsory notification now being tried at Sheffield. The Lord Mayor passed on the letter of protest to the Parliamentary subcommittee who passed it over to the sanitary committee, by whom it has been "entered on their minutes."

"What is White Pepper?"

A grocer was summoned before the Manchester county magistrates on Jan. 5th for selling pepper "not of the nature, substance, and quality demanded by the purchaser." It had been found on analysis to contain nearer 20 than 15 per cent. of bleached pepper husks. Pure white pepper consists of the kernel of the berry. The analysis was made by Mr. Collingwood Williams, one of the county analysts, in conjunction with Dr. Campbell Brown. The magistrates were presumably not satisfied with this analysis, for, after the adjournment, the stipendiary intimated that the bench had decided to try the case on the analysis submitted by the Government chemists, which showed that the proportion of husks, more or less bleached, was about 4 or 5 per cent. The case was adjourned that the prosecution might communicate with the Government chemists and if necessary call their experts. It would be interesting if experts could explain the great discrepancies often occurring between the Somerset House analyses of milk and other articles of food and those of the provinces. It would seem that sending samples to London in some way tended to their purification.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Poor-law Administration in Pontypool.

AT the last meeting of the Pontypool board of guardians Mr. F. T. Bircham, a Poor-law inspector of the Local Government Board, stated that in the last ten years the population of the union, which is now approaching 50,000, had increased 14 per cent. and the rateable value had increased 28 per cent. but the amount of pauperism had decreased 15 per cent. The expenditure, however, had increased nearly 20 per cent., accounted for principally by the improved accommodation provided for the sick poor. The Pontypool workhouse is a well-equipped institution, among other recent improvements having been the installation of electric light. Mr. Bircham spoke in complimentary terms of the administration of this institution. At the previous meeting of the board it was reported that at meal times only one mug was provided for six or seven persons in order to save the labour of washing up, but the master was very properly instructed to provide each inmate in the future with a separate mug.

By-laws under the Employment of Children Act.

In order to ascertain which employments exert the most pernicious influence upon children the medical officer of health for the Rhondda (Dr. J. D. Jenkins) has suggested to the district council that before framing by-laws under the Employment of Children Act it should obtain from the head teachers of elementary schools and from the school attendance officers a return giving particulars of all children employed for wages.

Bristol Workhouse Infirmary.

The proposals of the Bristol board of guardians in connexion with the provision of infirmary accommodation for the sick poor have already been referred to in THE LANCET[1] There are at present two workhouses in the city, each having accommodation for between 1100 and 1200 inmates, one at Stapleton and the other at Eastville. At the latter institution there are several buildings constructed of wood and of wood and iron which have been condemned as entirely unsuitable for the purpose to which they are put In 1901 it was decided to erect near the Stapleton workhouse a new infirmary and buildings for the imbeciles and for children and to abandon the Eastville workhouse. A competition among architects resulted in the selection of plans which received the approval of the Local Government Board and in September, 1902, a committee of the board of guardians recommended the acceptance of tenders for the erection of the buildings named at a cost of £130,000. This recommendation, however, only received the support of 25 members of the board and was not adopted. The next definite proposal of the board provided for the retention of the Eastville workhouse for the able-bodied and for the aged inmates who were in good health and for the treatment of the sick and infirm at Stapleton where a new building for 250 patients was to be erected, together with an entirely separate block for 500 imbeciles, this latter to be under independent management. This scheme was not approved by the Local Government Board which pointed out the difficulties connected with the adaptation of old buildings to modern requirements. A committee of the board of guardians was then formed to devise a scheme which would be acceptable to the Local Government Board as well as to those guardians who opposed the adoption of the infirmary scheme. This committee reported to a special meeting of the guardians held on Jan. 8th and its recommendations were adopted by 34 members of the board, 18 voting against them. This latest proposal provides for the retention of the Eastville workhouse (with the removal of the wooden structures and three of the five wood and iron pavilions) where would be housed the aged and infirm, the able-bodied, casuals, and married couples; for the adaptation of the block at present used for imbeciles as an infirmary for the chronic sick; for the erection of four new pavilions for the acutely sick, and of a block for lying-in cases together with new receiving wards. The cost of these extensions is estimated at £50,565 and there would be a total accommodation for 1354 inmates. At the Stapleton workhouse it is proposed to make alterations at a cost of £6360 which would make the existing accommodation sufficient for 1398 inmates who would include the acute sick, the aged and infirm, able bodied women with babies, casuals, and married couples. For the imbeciles and epileptics it is proposed to establish a separate institution to accommodate 724 inmates at a cost of £100,000. The total expenditure would thus be nearly £157,000 and there would be accommodation in the three institutions for 3476 inmates. The opponents of this scheme, which has yet to receive the sanction of the Local Government Board, point out that the expenditure of a large sum of money upon altering existing buildings can never be satisfactory and that there would still be two workhouses with a duplication of administrative expenses.

[1] THE LANCET, Oct. 4th, 1902, p. 952, and May 30th, 1903, p. 1549.

Low Death-rates in the West of England.

The death rates in the city of Bristol during 1903 compare very favourably with those recorded in previous years. In 1893 the death-rate from all causes was 18 8 per 1000 and since then there has been a steady fall until last year when 14 2 per 1000 was recorded. The death-rate from the principal zymotic diseases was 1·1 per 1000 in 1903, compared with an average rate during the previous ten years of 1·9 per 1000. Still more satisfactory is the low rate of infantile mortality. In 1899 this was equal to 157 per 1000 births and in no recent year has there been a lower rate than 130 per 1000 births, but in 1903 the number of deaths under one year was equal to 116 per 1000 births. At the meeting of the Wellington (Somerset) urban district council, held on Jan. 7th, it was reported that 91 deaths occurred in Wellington during 1903, corresponding to a rate of 12·45 per 1000, the lowest since the records had been kept. At the meeting of the Bath sanitary committee, held on Jan. 6th, it was stated that 751 deaths occurred at Bath during 1903, being the lowest number of deaths registered since records have been kept; in 1902 the deaths numbered 911. At the meeting of the Chard town council, held on Jan. 7th, it was reported by the medical officer of health that the death-rate for 1903 was 13 per 1000, being the lowest rate for the past 12 years. Only two deaths occurred from the zymotic diseases—namely, one from diphtheria and one from whooping-cough.
